If one day's work were necessary in order to keep one worker alive for one day, then capital would not exist, because the working day would then exchange for its own product, so that capital could not realize itself and hence could not maintain itself as capital. The self-preservation of capital is its self-realization. If capital also had to work in order to live, then it would not maintain itself as capital but as labour. Property in raw materials and instruments of labour would be merely *nominal*; economically they would belong to the worker as much as to the capitalist, since they would create *value* for the capitalist only in so far as he himself were a worker. He would relate to them therefore not as capital, but as simple material and means of labour, like the worker himself does in the production process. If, however, only half a working day is necessary in order to keep one worker alive one whole day, then the surplus value of the product is self-evident, because the capitalist has paid the price of only half a working day but has obtained a whole day objectified in the product; thus has exchanged *nothing* for the second half of the work day. The only thing which can make him into a capitalist is not exchange, but rather a process through which he obtains *objectified labour time*, i.e. *value*, without exchange. Half the working day costs capital nothing; it thus obtains a value for which it has given no equivalent. And the multiplication of values can take place only if a value in excess of the equivalent has been obtained, hence *created*.

Surplus value in general is value in excess of the equivalent. The equivalent, by definition, is only the identity of value with itself. Hence surplus value can never sprout out of the equivalent; nor can it do so originally out of circulation; it has to arise from the production process of capital itself. The matter can also be expressed in this way: if the worker needs only half a working day in order to live a whole day, then, in order to keep alive as a worker, he needs to work only half a day. The second half of the labour day is forced labour; surplus-labour. What appears as surplus value on capital's side appears identically on the worker's side as surplus labour in excess of his requirements as worker, hence in excess of his immediate requirements for keeping himself alive. The great historic quality of capital is to create this *surplus labour*, superfluous labour from the standpoint of mere use value, mere subsistence; and its historic destiny [*Bestimmung*] is fulfilled as soon as, on one side, there has been such a development of needs that surplus labour above and beyond necessity has itself become a general need arising out of individual needs themselves – and, on the other side, when the severe discipline of capital, acting on succeeding generations [*Geschlechter*], has developed general industriousness as the general property of the new species [*Geschlecht*] – and, finally, when the development of the productive powers of labour, which capital incessantly whips onward with its unlimited mania for wealth, and of the sole conditions in which this mania can be realized, have flourished to the stage where the possession and preservation of general wealth require a lesser labour time of society as a whole, and where the labouring society relates scientifically to the process of its progressive reproduction, its reproduction in a constantly greater abundance; hence where labour in which a human being does what a thing could do has ceased. Accordingly, capital and labour relate to each other here like money and commodity; the former is the general form of wealth, the other only the substance destined for immediate consumption. Capital's ceaseless striving towards the general form of wealth drives labour beyond the limits of its natural paltriness [*Naturbedürftigkeit*], and thus creates the material elements for the development of the rich individuality which is as all-sided in its production as in its consumption, and whose labour also therefore appears no longer as labour, but as the full development of activity itself, in which natural necessity in its direct form has disappeared; because a historically created need has taken the place of the natural one. This is why *capital is productive; i.e. an essential relation for the development of the social productive forces.* It ceases to exist as such only where the development of these productive forces themselves encounters its barrier in capital itself.

The Times of November 1857 contains an utterly delightful cry of outrage on the part of a West-Indian plantation owner. This advocate analyses with great moral indignation – as a plea for the re-introduction of Negro slavery – how the *Quashees* (the free blacks of Jamaica) content themselves with producing only what is strictly necessary for their own consumption, and, alongside this 'use value', regard loafing (indulgence and idleness) as the real luxury good; how they do not care a damn for the sugar and the fixed capital invested in the plantations, but rather observe the planters' impending bankruptcy with an ironic grin of malicious pleasure, and even exploit their acquired Christianity as an embellishment for this mood of malicious glee and indolence. [39] They have ceased to be slaves, but not in order to become wage labourers, but, instead, self-sustaining peasants working for their own consumption. As far as they are concerned, capital does not exist as capital, because autonomous wealth as such can exist only either on the basis of *direct* forced labour, slavery, or *indirect* forced labour, *wage labour*. Wealth confronts direct forced labour not as capital, but rather as *relation of domination* [*Herrschaftsverhältnis*]; thus, the relation of domination is the only thing which is reproduced on this basis, for which wealth itself has value only as gratification, not as wealth itself, and which can therefore never create *general industriousness.* (We shall return to this relation of slavery and wage labour.) [40]

Surplus value. *Ricardo. Physiocrats. A. Smith. Ricardo*

The difficulty of grasping the creation of value shows itself (1) in those modern English economists who accuse Ricardo of not having understood the surplus, the *surplus value* (see *Malthus on value*, who at least tries to proceed scientifically), [41] whereas, among all the economists, Ricardo alone understood it, as is demonstrated by his polemic against A. Smith's confusion of the determination of value by wages and by the labour time objectified in the commodity. The newcomers are just plain simpletons. However, Ricardo himself often gets into confusion, because, although he well understands that the creation of surplus value is the presupposition of capital, he often goes astray in conceiving the multiplication of values on any basis other than the investment of *additional objectified labour time* in the same product, in other words, on any basis other than when production becomes *more difficult*. Hence the absolute antithesis in his thinking between *value* and *wealth*. Hence the one-sidedness of his theory of ground rent; his erroneous theory of international trade, which is supposed to produce only use value (which he calls wealth), not exchange value. [42] The only avenue for the increase of values as such, apart from the *growing difficulty of production* (theory of rent), remains population growth (the natural increase among workers resulting from the growth of capital), although he himself never plainly summarized this relation. The basic mistake, that he never investigates where actually the distinction between the determination of value by wages and that by objectified labour comes from. Money and exchange itself (circulation) therefore appear only as purely formal elements in his economics; and although, according to him, economics is concerned *only* with exchange value, profit etc. appears there *only* as a percentage share of the product, which happens just as much on the basis of slavery. He never investigated the form of the mediation.

(2) *The Physiocrats.* Here the difficulty of grasping capital, the self-realization of value, hence the surplus value created by capital in the act of production, presents itself in tangible form, and this was necessarily so among the fathers of modern economics, just as was the case with the creation of surplus value in Ricardo, which he conceives in the form of rent, during the final classical conclusion of this economics. It is at bottom the question of the concept of capital and of wage labour, and therefore the fundamental question which presents itself at the threshold of the system of modern society. The Monetary System had understood the autonomy of value only in the form in which it arose from simple circulation – *money*; it therefore made this *abstract form* of wealth into the exclusive object [*Objekt*] of nations which were just then entering into the period in which the *gaining of wealth as such* appeared as the aim of society itself. Then came the Mercantile System, an epoch where industrial capital and hence wage labour arose in manufactures, and developed in antithesis to and at the expense of non-industrial wealth, of feudal landed property. [The Mercantilists] already have faint notions of money as capital, but actually again only in the form of money, of the circulation of *mercantile* capital, of capital which *transforms* itself into *money*. Industrial capital has value for them, even the highest value – as a means, not as wealth itself in its productive process – because it creates mercantile capital and the latter, via circulation, becomes money. Labour in manufactures – i.e. at bottom industrial labour, but agricultural labour was and appeared to them, in antithesis, as chiefly productive of use values; raw products, processed, are more valuable, because in a clearer form, likewise more suitable for circulation, commerce; creating more money for the mercantile form (in this regard the historic view of wealth of non-agricultural peoples such as Holland, for example,

in antithesis to that of the agricultural, feudal; agriculture did not appear at all in industrial form, but in feudal, hence as source of feudal, not of bourgeois wealth). Thus one form of wage labour, the industrial, and one form of capital, the industrial, were recognized as sources of wealth, but only in so far as they produced money. Exchange value itself therefore not yet conceived in the form of capital. Now the *Physiocrats*. They distinguish between capital and money, and conceive it in its general form as autonomous exchange value which preserves and increases itself in and through production. They also therefore examine the relation for itself, not merely as a moment of simple circulation, but rather as its presupposition which constantly rises out of it to become its presupposition again. They are therefore the fathers of modern economics. They also understand that the creation of surplus value by wage labour is the self-realization [*Selbstverwertung*], i.e. the realization [*Verwirklichung*] of capital. But how does labour act as a means to produce a surplus value out of capital, i.e. already-present value? Here they let the form drop altogether and only look at the simple production process. Hence only that labour can be productive which takes place in the kind of field where the natural force of the instrument of labour tangibly permits the labourer to produce more value than he consumes. Surplus value therefore does not arise from labour as such, but rather from the natural forces which labour uses and conducts – agriculture. This is therefore the only *productive labour*, for they have come so far that [they consider that] *only labour which creates surplus value is productive* (that surplus value has to express itself in a material product is a crude view which still occurs in A. Smith. [43] Actors are productive workers, not in so far as they produce a play, but in so far as they increase their employer's wealth. But what sort of labour takes place, hence in what form labour materializes itself, is absolutely irrelevant for *this relation*. It is not irrelevant, again, from later points of view); but this surplus value surreptitiously transforms itself into a quantity of use value coming out of production, larger than that which is consumed in it. This multiplication of use values, the excess of the product above that which has to serve as a means for new production – of which a part can therefore be consumed unproductively – appears tangibly only in the relation between the natural seed and its product. Only a part of the harvest has to be directly returned to the soil as seed; products found in nature, the elements air, water, earth, light, and added substances such as fertilizer, then recreate the seed again in multiplied quantity as grain etc. In short, human labour has only to conduct the chemical processes (in agriculture), and in part also to promote them mechanically, or promote the reproduction of life itself (cattle-raising) in order to obtain the surplus, i.e. to transform the identical natural substances from a useless into a valuable form. An over-abundance of agricultural products (grain, cattle, raw materials) is therefore the true form of general wealth. From the economic viewpoint, therefore, *rent* is the only form of wealth. Thus it is that the first prophets of capital conceive only the not-capitalists, the *feudal landed proprietors*, as the representatives of *bourgeois* wealth. The consequence, the levy of all taxes on rent, is then, however, entirely to the advantage of bourgeois capital. The bourgeois glorify feudalism in theory – many a feudal figure, like the elder Mirabeau [44] has been duped by this – only in order to ruin it in actual practice. All other values merely represent raw material + labour; labour itself represents grain or other products of the soil, which labour consumes; hence the factory worker etc. adds no more to the raw material than he consumes in raw materials. Therefore, his labour as well as his employer create no additional wealth – wealth being the surplus above the commodities consumed in production – but merely give it forms more pleasant and useful for consumption. At that time the utilization of natural energy in industry had not developed, nor the division of labour etc. which increases the natural force of labour itself. This was the case, however, in A. Smith's time. With him, therefore, labour in principle the source of value, likewise of wealth, but actually labour too posits surplus value only in so far as in the division of labour the surplus appears as just as much a gift of nature, a natural force of society, as the soil with the Physiocrats. Hence the weight A. Smith lays on the division of labour. *Capital*, on the other hand, appears to him – because, although he defines labour as productive of value, he conceives it as use value, as productivity for-itself [*für sich seiend*], as *human* natural force in general (this distinguishes him from the Physiocrats), but not as wage labour, not in its *specific* character as form in antithesis to capital – not as that which contains wage labour as its internal contradiction from its origin, but rather in the form in which it emerges from circulation, as money, and is therefore created out of circulation, by *saving*. Thus capital does not originally realize itself – precisely because the appropriation of alien labour [*fremde Arbeit*] is not itself included in its concept. Capital appears only *afterwards*, after already having been presupposed as *capital* – a vicious circle – as *command over alien labour*. Thus, according to A. Smith, labour should actually have its own product for wages, wages should be = to the product, hence labour should not be wage labour and capital not capital. Therefore, in order to introduce profit and rent as original elements of the cost of production, i.e. in order to get a surplus value out of the capitalist production process, he presupposes them, in the clumsiest fashion. The capitalist does not want to give the use of his capital for nothing; the landowner, similarly, does not want to give land and soil over to production for nothing. They want something in return. This is the way in which they are introduced, with their demands, as historical facts, but not explained. Wages are actually the *only economically* justifiable, because necessary, element of production costs. Profit and rent are only *deductions* from wages, arbitrarily wrested by force in the historical process by capital and landed property, and justified *by law*, not economically. But on the other side, since he [Adam Smith] then confronts labour with the means and materials of production in the form of landed property and capital, as independent entities, he has essentially posited labour as wage labour. Therefore contradictions. Hence his vacillation in the determination of value; the placing of profit and ground rent on the same level; erroneous views about the influence of wages on prices etc. Now Ricardo (see 1). [45] With him, however, wage labour and capital are again conceived as a natural, not as a historically specific social form [*Gesellschaftsform*] for the creation of wealth as use value; i.e. their form as such, precisely because it is natural, is *irrelevant*, and is not conceived in its *specific* relation to the form of wealth, just as wealth itself, in its exchange-value form, appears as a merely formal mediation of its material composition; thus the specific character of bourgeois wealth is not grasped – precisely because it appears there as the adequate form of wealth as such, and thus, although *exchange value* is the point of departure, the *specific economic forms of exchange* themselves play no role at all in his economics. Instead, he always speaks about distribution of the general product of labour and of the soil among the three classes, as if the form of wealth based on *exchange value* were concerned only with *use value*, and as if exchange value were merely a ceremonial form, which vanishes in Ricardo just as money as medium of circulation vanishes in exchange. Therefore, in order to bring out the true laws of economics, he likes to refer to this relation of money as a merely formal one. Hence also his weakness in the doctrine of money proper.

The exact development of the concept of capital [is] necessary, since it [is] the fundamental concept of modern economics, just as capital itself, whose abstract, reflected image [is] its concept [*dessen abstraktes Gegenbild sein Begriff*], [is] the foundation of bourgeois society. The sharp formulation of the basic presuppositions of the relation must bring out all the contradictions of bourgeois production, as well as the boundary where it drives beyond itself.

<It is important to note that wealth as such, i.e. bourgeois wealth, is always expressed to the highest power as exchange value, where it is posited as *mediator*, as the mediation of the extremes of exchange value and use value themselves. This intermediary situation [*Mitte*] always appears as the *economic* relation in its completeness, because it comprises the opposed poles, and ultimately always appears as a one-sidedly higher power *vis-à-vis* the extremes themselves; because the movement, or the relation, which *originally* appears as mediatory between the extremes necessarily develops dialectically to where it appears as mediation with itself, as the subject [*Subjekt*] for whom the extremes are merely its moments, whose autonomous presupposition it suspends in order to posit itself, through their suspension, as that which alone is autonomous. Thus, in the religious sphere, Christ, the mediator between God and humanity – a mere instrument of circulation between the two – becomes their unity, God-man, and, as such, becomes more important than God; the saints more important than Christ; the popes more important than the saints. Where it is posited as middle link, exchange value is always the total economic expression, itself one-sided against the extremes; e.g. money in simple circulation; capital itself as mediator between production and circulation. Within capital itself, one form of it in turn takes up the position of use value against the other as exchange value. Thus e.g. does industrial capital appear as producer as against the merchant, who appears as circulation. Thus the former represents the material [*stofflich*], the latter the formal side, i.e. wealth as wealth. At the same time, mercantile capital is itself in turn the mediator between production (industrial capital) and circulation (the consuming public)

or between exchange value and use value, where both sides are posited alternately, production as money and circulation as use value (consuming public) or the former as use value (product) and the latter as exchange value (money). Similarly within commerce itself: the wholesaler as mediator between manufacturer and retailer, or between manufacturer and agriculturalist, or between different manufacturers; he is the same mediator at a higher level. And in turn, in the same way, the commodity brokers as against the wholesalers. Then the banker as against the industrialists and merchants; the joint-stock company as against simple production; the financier as mediator between the state and bourgeois society, on the highest level. *Wealth as such* presents itself more distinctly and broadly the further it is removed from direct production and is itself mediated between poles, each of which, considered for itself, is already posited as economic form. Money becomes an end rather than a means; and the higher form of mediation, as capital, everywhere posits the lower as itself, in turn, labour, as merely a source of surplus value. For example, the bill-broker, banker etc. as against the manufacturers and farmers, which are posited in relation to him in the role of labour (of use value); while he posits himself toward them as capital, extraction of surplus value; the wildest form of this, the financier.>

Capital is direct unity of product and money or, better, of production and circulation. Thus it itself is again something *immediate*, and its development consists of positing and suspending itself as this unity – which is posited as a specific and therefore simple relation. The unity at first appears in capital as something *simple*.

<Ricardo’s reasoning is simply this: products are exchanged for one another – hence capital for capital – according to the amounts of objectified labour contained in them. A day’s work is always exchanged for a day’s work. This is presupposition. Exchange itself can therefore be entirely left out. The product – capital posited as product – is exchange value *in itself*, to which exchange merely adds form; formal form with him. The only question is now in what *proportions* this product is divided up and distributed. Whether these *proportions* are regarded as specific quotas of the presupposed exchange value, or of its content, material wealth, [is] the same thing. Moreover, since exchange as such is merely circulation – money as circulation – it is better to

abstract from it altogether, and to examine only the proportions of material wealth which have been distributed within the production process or because of it to the various factors. In the *exchange* form, all value etc. is merely *nominal*; it is real only in the form of the *proportion*. Exchange as a whole, to the extent that it creates no greater *material* variety, is *nominal*. Since a full day's work is always exchanged for a full day's work, the sum of *values* remains the same – the growth in the forces of production affects only the content of wealth, not its form. An increase of values can arise, therefore, only out of an increasing difficulty in production – and this can take place only where the forces of nature no longer afford an equal service to equal quantities of human labour, i.e. where the fertility of the natural elements decreases – in agriculture. The decline of profits is therefore caused by rent. [46] Firstly the false presupposition that a *full day's work* is always worked in all social conditions; etc. etc. (see above [47]).>

Surplus value and productive force. Relation when these increase. – Result. – Productive force of labour is productive force of capital. – In proportion as necessary labour is already diminished, the realization of capital becomes more difficult

We have seen: The worker needs to work only e.g. half a working day in order to live a whole one; and hence to be able to begin the same process again the next day. Only half a day's work is objectified in his labouring capacity – to the extent that it exists in him as someone *alive*, or as a *living* instrument of labour. The worker's entire living day (day of life) is the static result, the objectification of half a day's work. By appropriating the entire day's work and then consuming it in the production process with the materials of which his capital consists, but by giving in exchange only the labour objectified in the worker – i.e. half a day's work – the capitalist creates the surplus value of his capital; in this case, half a day of objectified labour. Now suppose that the productive powers of labour double, i.e. that the same labour creates double the *use value* in the same time. (For the moment, use value is defined in the present relation as only that which the worker consumes in order to stay alive as a worker; the quantity of the means of life for which, through the mediation of money, he exchanges the labour objectified in his living labouring capacity.) The worker would then have to work only 1/4 day in order to live a full day; the capitalist then needs to give the worker only 1/4 day's objectified labour in exchange, in order to increase his surplus value in the production process from 1/2 to 3/4; so that he would gain 3/4 day's objectified labour instead of 1/2. At the end of the production process, the value of the capital would have risen by 3/4 instead of by 2/4. Thus the capitalist would have to make the workers work only 3/4 day, in order to add the same surplus value – that of 1/2 or 2/4 objectified labour – to his capital. However, as representative of the general form of wealth – money – capital is the endless and limitless drive to go beyond its limiting barrier. Every boundary [*Grenze*] is and has to be a barrier [*Schranke*] for it. [48] Else it would cease to be capital – money as self-reproductive. If ever it perceived a certain boundary not as a barrier, but became comfortable within it as a boundary, it would itself have declined from exchange value to use value, from the general form of wealth to a specific, substantial mode of the same. Capital as such creates a specific surplus value because it cannot create an infinite one all at once; but it is the constant movement to create more of the same. The quantitative boundary of the surplus value appears to it as a mere natural barrier, as a necessity which it constantly tries to violate and beyond which it constantly seeks to go. * Therefore (quite apart from the factors entering in later, competition, prices etc.) the capitalist will make the worker work not only 3/4 day, because the 3/4 day bring him the *same surplus value* as the whole day did before, but rather he will make him work the full day; and the increase in the productive force which allows the worker to work for 1/4 day and live a whole day now expresses itself simply in that he now has to work 3/4 day for capital, whereas before he worked for it only 2/4 day. The increased productive force of his labour, to the extent that it is a shortening of the time required to replace the labour objectified in him (for use value, subsistence), appears as a lengthening of the time he labours for the realization of capital (for exchange value). From the worker's standpoint, he now has to do a surplus labour of 3/4 day in order to live a full day, while before he only had to do a surplus labour of 2/4 day. The increase, the doubling of the productive force, has increased his surplus labour by 1/4 [day]. One remark here: the productive force has doubled, the surplus labour the worker has to do has not doubled, but has only grown by 1/4 [day]; nor has capital's surplus value doubled; but it, too, has grown by only 1/4 [day]. This shows, then, that surplus labour (from the worker's standpoint) or surplus value (from capital's standpoint) does not grow in the same numerical proportion as the productive force. Why? The doubling in the productive force is the reduction of necessary labour (for the worker) by 1/4 [day], hence also the [increase of the] production of surplus value by 1/4, because the original relation was posited as 1/2. If the worker had to work, originally, 2/3 day in order to live one full day, then the surplus value would have been 1/3, and the surplus labour the same. The doubling in the productive force of labour would then have enabled the worker to restrict his necessary labour to half of 2/3 or 2/(3 × 2), 2/6 or 1/3 day, and the capitalist would have gained 1/3 [day] of value. But the total surplus labour would have become 2/3 [day]. The doubling of the productive force, which resulted in 1/4 [day] surplus value and surplus labour in the first example, would now result in 1/3 [day] surplus value or surplus labour. The multiplier of the productive force – the number by which it is multiplied – is therefore not the multiplier of surplus labour or of surplus value; but rather, if the original relation of the labour objectified in the labour price was 1/2 of the labour objectified in 1 working day, which always appears as the limit, † then the doubling is equal to the division of 1/2 by 2 (in the original relation), i.e. 1/4. If the original relation was 2/3, then the doubling equals the division of 2/3 by 2 = 2/6 or 1/3. The multiplier of the productive force is thus never the multiplier but always the divisor of the original relation, not the multiplier of its numerator but of its denominator. If it were the former, then the multiplication of the productive force would correspond to the multiplication of the surplus value. Instead, the surplus value is always equal to the division of the original relation by the multiplier of the productive force. If the original relation was 8/9, i.e. the worker needs 8/9 of a working day to live, so that capital gains only 1/9 in its exchange with living labour, if surplus labour equals 1/9, then the worker can now live from half of 8/9 of a working day, i.e. with 8/18 = 4/9 (whether we divide the numerator or multiply the denominator the same thing), and the capitalist, who orders a full day’s work, would have a total surplus value of 4/9 working day; subtracting the original surplus value of 1/9 from this leaves 3/9 or 1/3. The doubling of the productive force therefore = here an increase in surplus value or surplus time by 1/3. This is simply because the surplus value is always equal to the relation between the whole working day and that part of the working day necessary to keep the worker alive. The unit in which surplus value is calculated is always a fraction, i.e. the given part of a day which exactly represents the price of labour. If that is = 1/2, then the increase in the productive force = the reduction of necessary labour to 1/4; if it is = 1/3, then reduction of necessary labour to 1/6; hence in the first, the total surplus value = 3/4; in the second = 5/6; the relative surplus value, i.e. relative to that present before, in the first case = 1/4, in the second = 2/6 or 1/3. Therefore the value of capital does not grow in the same proportion as the productive force increases, but in the proportion in which the increase in the productive force, the multiplier of productive force, divides the fraction of the working day which expresses the part of the day belonging to the worker. The extent to which the productive force of labour increases the value of capital thus depends on the original relation between the portion of labour objectified in the worker and his living labour. This portion is always expressed as a fractional part of the whole working day, 1/3, 2/3, etc. The increase in productive force, i.e. its multiplication by a given amount, is equal to a division of the numerator or the multiplication of the denominator of this fraction by the same amount. Thus the largeness or smallness of the increase of value depends not only on the number which expresses the multiplication of the productive force, but equally on the previously given relation which makes up the part of the work day belonging to the price of labour. If this relation is 1/3, then the doubling of the productive force of the working day = a reduction of the same to 1/6; if it is 2/3, then reduction to 2/6. The objectified labour contained in the price of labour is always equal to a fractional part of the whole day; always arithmetically expressed as a fraction; always a relation between numbers, never a simple number. If the productive force doubles, multiplies by 2, then the worker has to work only 1/2 of the previous time in order to get the price of labour out of it; but how much labour time he still needs for this purpose depends on the first, given relation, namely on the time which was required before the increase in productive force. The multiplier of the productive force is the divisor of this original fraction. Value or surplus labour therefore does not increase in the same numerical relation as productive force. If the original relation is 1/2 and the productive force is doubled, then the *necessary* (for the worker) labour time reduces itself to 1/4 and the surplus value grows by only 1/4. If the productive force is quadrupled, then the original relation becomes 1/8 and the value grows by only 1/8. The value can never be equal to the entire working day; i.e. a certain part of the working day must always be exchanged for the labour objectified in the worker. Surplus value in general is only the relation of living labour to that objectified in the worker; *one member of the relation must therefore always remain*. A certain relation between increase in productive force and increase of value is already given in the fact that the relation is constant as a relation, although its factors vary. We see therefore, on one side, that relative surplus value is exactly equal to relative surplus labour; if the working day was 1/2 and the productive force doubles, then the part belonging to the worker, *necessary labour*, reduces itself to 1/4 and the new value is also exactly 1/4; but the total value is now 3/4. While surplus value rose by 1/4, i.e. in the relation of 1:4, the total surplus value = 3/4 = 3:4. Now if we assume that 1/4 was the original *necessary* working day, and a doubling in productive force took place, then necessary labour is reduced to 1/8 and surplus labour or surplus value exactly = 1/8 = 1:8. The total surplus value by contrast = 7:8. In the first example the original total surplus value = 1:2 (1/2) and then rose to 3:4; in the second case the original total surplus value was 3/4 and has now risen to 7:8 (7/8). In the first case it has grown from 1/2 or 2/4 to 3/4; in the second from 3/4 or 6/8 to 7/8; in the first case by 1/4, in the second by 1/8; i.e. in the first case it rose twice as much as in the second: but in the first case the total surplus value is only 3/4 or 6/8 while it is 7/8 in the second, i.e. 1/8 more.

[*] The barrier appears as an accident which has to be conquered. This is apparent on even the most superficial inspection. If capital increases from 100 to 1,000, then 1,000 is now the point of departure, from which the increase has to begin; the tenfold multiplication, by 1,000% counts for nothing; profit and interest themselves become capital in turn. *What appeared as surplus value now appears us simple presupposition etc.*, as included in its *simple composition.*

[†] Messrs the manufacturers have, however, also prolonged it into the night, *ten hours' bill*. See the report of Leonard Horner. [49] The working day itself does not recognize daylight as a limit; it can be lengthened *deep into the night*; this belongs to the chapter on *wages*.

Let *necessary labour* be 1/16, then total surplus value = 15/16; which was 5/8 = 10/16 in the previous relation; thus the total surplus value presupposed is by 5/16 higher than in the previous case. [50] Now let the productive force double, then necessary labour = 1/32; which was previously = 2/32 (1/16); hence surplus time has risen by 1/32, surplus value by the same proportion. As regards the total surplus value, which was 15/16 or 30/32, this is now 31/32. Compared to the earlier relation (where *necessary* labour was 1/4 or 8/32), the total surplus value is now 31/32, whereas it was only 30/32 earlier, hence grew by 1/32. But regarded relatively, the doubling of production increased it in the first case by 1/8 or 4/32, while it has now increased by only 1/32, i.e. by 3/32 less.

If *necessary labour* had already been reduced to 1/1,000, then the total surplus value would be = 999/1,000. Now if the productive force increased a thousandfold, then necessary labour would decline to 1/1,000,000 working day and the total surplus value would amount to 999,999/1,000,000 of a working day; whereas before this increase in productive force it amounted to only 999/1,000 or 999,000/1,000,000; it would thus have grown by 999/1,000,000 = 1/11 (with the addition of 1/(11 + 1/999), [51] i.e. the thousandfold increase in productive force would have increased the total surplus by not even 1/11, i.e. not even by 3/33, whereas in the previous case it rose by 1/32 owing to a mere doubling of the productive force. If necessary labour falls from 1/1,000 to 1/1,000,000, then it falls by exactly 999/1,000,000 (for 1/1,000 = 1,000/1,000,000), i.e. by the surplus value.

If we summarize this, we find:

Firstly: The increase in the productive force of living labour increases the *value* of capital (or diminishes the value of the worker) not because it increases the quantity of products or use values created by the same labour – the productive force of labour is its natural force – but rather because it diminishes *necessary* labour, hence, in the same relation as it diminishes the former, it creates *surplus labour* or, what amounts to the same thing, surplus value; because the surplus value which capital obtains through the production process consists only of the excess of surplus labour over *necessary labour*. The increase in productive force can increase surplus labour – i.e. the excess of labour objectified in capital as product over the labour objectified in the exchange value of the working day – only to the extent that it diminishes the relation of *necessary labour* to *surplus labour*, and only in the proportion in which it diminishes this relation. Surplus value is exactly equal to surplus labour; the increase of the one [is] exactly measured by the diminution of *necessary labour*.

Secondly: The surplus value of capital does not increase as does the multiplier of the productive force, i.e. the amount to which the productive force (posited as unity, as multiplicand) increases; but by the surplus of the fraction of the living work day which originally represents necessary labour, in excess over this same fraction divided by the multiplier of the productive force. Thus if *necessary labour* = 1/4 of the living work day and the productive force doubles, then the value of capital does not double, but grows by 1/8; which is equal to 1/4 or 2/8 (the original fraction of the work day which represents necessary labour) − 1/4 divided by 2, or = 2/8 minus 1/8 = 1/8. (That value doubles itself can also be expressed, it grows 4/2 [-fold] or 16/8 [-fold]. Its growth would relate to that of the productive force by 1:16. (That is it!) [52] If the fraction was 1/1,000 and the productive force increases a thousandfold, then the value of capital does not grow a thousandfold, but rather by far less than 1/11; it grows by 1/1,000 − 1/1,000,000, i.e. by 1,000/1,000,000 − 1/1,000,000 = 999/1,000,000.)

Thus the *absolute sum* by which capital increases its value through a given increase of the productive force depends on the *given fractional part* of the working day, on the fractional part of the working day which represents *necessary labour*, and which therefore expresses the original relation of necessary labour to the living work day. The increase in productive force in a given relation can therefore increase the value of capital differently e.g. in the *different countries*. A general increase of productive force in a given relation can increase the value of capital differently in the different branches of industry, and will do so, depending on the different relation of *necessary labour* to the living work day in these branches. This relation would naturally be the same in all branches of business in a system of free competition, if labour were simple labour everywhere, hence *necessary labour* the same. (If it represented the same amount of objectified labour.)

Thirdly: The larger the surplus value of capital *before the increase of productive force*, the larger the amount of presupposed surplus labour or surplus value of capital; or, the smaller the fractional part of the working day which forms the equivalent of the worker, which expresses necessary labour, the smaller is the increase in surplus value which capital obtains from the increase of productive force. Its surplus value rises, but in an ever smaller relation to the development of the productive force. Thus the more developed capital already is, the more surplus labour it has created, the more terribly must it develop the productive force in order to realize itself in only smaller proportion, i.e. to add surplus value – because its barrier always remains the relation between the fractional part of the day which expresses *necessary labour*, and the entire working day. It can move only within these boundaries. The smaller already the fractional part falling to *necessary labour*, the greater the *surplus labour*, the less can any increase in productive force perceptibly diminish necessary labour; since the denominator has grown enormously. The self-realization of capital becomes more difficult to the extent that it has already been realized. The increase of productive force would become irrelevant to capital; realization itself would become irrelevant, because its proportions have become minimal, and it would have ceased to be capital. If necessary labour were 1/1,000 and the productive force tripled, then it would fall to only 1/3,000 or surplus labour would have increased by only 2/3,000. But this happens not because wages have increased or the share of labour in the product, but because it has *already* fallen so low, regarded in its relation to the product of labour or to the living work day. *

> * The labour objectified in the worker here shows itself as a fraction *of his own living work day*; for that is the same as [the proportion] in which the objectified labour which he obtains from capital as wages stands to the entire working day.

(All these statements correct only in this abstraction for the relation from the present standpoint. Additional relations will enter which modify them significantly. The whole, to the extent that it proceeds entirely in generalities, *actually already belongs in the doctrine of profit.*)

So much in general for the time being: the development of the productive force of labour – first the positing of surplus labour – is a necessary condition for the growth of value or the realization of capital. As the infinite urge to wealth, it strives consistently towards infinite increase of the productive forces of labour and calls them into being. But on the other hand, every increase in the productive force of labour – leaving aside the fact that it increases the use values for the capitalist – is an increase in the productive force of capital and, from the present standpoint, is a productive force of labour only in so far as it is a productive force of capital.

Concerning increases in the value of capital

This much is already clear, can at least be mentioned in anticipation: the increase in the productive force does not in and by itself increase prices. For example the bushel of wheat. If a half of a working day objectifies itself in one bushel of wheat, and if this is the worker’s price, then the surplus labour can only produce 2 bushels of wheat. Thus 2 bushels of wheat [is] the value of one working day, and if that = 26s. in money, = 26s. Each bushel = 13s. Now if the productive force doubles, then the bushel of wheat no more than = 1/4 working day; = 6 1/2s. With the productive force, the price of this fractional part of the commodity fell. But the total price remained; but now a surplus of 3/4 working day. Every fourth = 1 bushel wheat = 6 1/2s. Thus the total product = 26s. = 4 bushels. Same as before. The value of the capital increased from 13s. to 19 1/2s. The value of labour diminished from 13s. to 6 1/2s.; material production rose from 2 bushels to 4. Now 19 1/2. [53] Now, if the force of production were to double also in gold production, so that, if 13s. were the product of half a working day and this half a day were the *necessary labour* before; now 1/4 [working day] produces 52s. or 52 − 13 = 39s. more. 1 bushel of wheat now = 13s.; the same fractional price afterwards as before; but the total product = 52s.; before only = 26s. On the other hand, the 52s. would now buy 4 bushels, while the 26, earlier, bought only 2.

Well. First of all it is clear that if capital has already raised surplus labour to the point where the entire living work day is consumed in the production process (and we here assume the working day to be the natural amount of labour time which the worker is able to put at the disposal of capital; this is always only for a *specific time*, i.e. *specific labour time*), then an increase in the productive force cannot increase labour time, nor, therefore, objectified labour time. The product objectifies one working day, whether the necessary time of labour is represented by 6 or 3 hours, by 1/2 or 1/4 of the working day. The surplus value of capital has grown; i.e. its value relative to the worker – for if it was only = 2/4 before, it is now = to 3/4 of objectified labour time; but its value increased not because the *absolute* but because the *relative amount of labour* grew; i.e. the total amount of labour did not grow; the working day is as long before as after; hence no absolute increase in surplus time (surplus labour time); rather the *amount of necessary labour decreased*, and that is how relative surplus labour increased. The worker in fact worked a whole day before, but only 1/2 day of surplus time; afterwards, as before, he works the whole day, but 3/4 of a day of surplus time. To that extent, therefore, the price (presupposing this as its gold and silver value), or the exchange value of capital, has not increased with the doubling of the productive force. This therefore concerns the *rate of profit*, not the price of the product or the value of the capital, which became a commodity again in the product. But in fact the absolute values also increase in this manner, because that part of wealth which is posited as capital – as self-realizing value – also increases. (*Accumulation of capitals*.) Take our earlier example. Let *capital* = 100 thalers, and let it decompose in the production process into the following parts: 50 thalers cotton, 40 thalers wages, 10 thalers instrument. Assume at the same time, in order to simplify the arithmetic, that the entire instrument of labour is consumed in one act of production (and this is quite beside the point here, so far), so that its entire value would reappear in the form of the product. Suppose in this case that the 40 thalers which go to labour express a labour time objectified in living labouring capacity of, say, 4 hours, giving capital 8 hours. Presupposing the instrument and the raw material, the total product would amount to 100 thalers, if the worker works only 4 hours, i.e. if the raw material and the instrument were his property and he worked for 4 hours only. He would increase the 60 thalers by 40, which he could consume, since firstly he replaces the 60 thalers in raw material and instrument required for production, and then adds a surplus value of 40 thalers as reproduction of his own living labour capacity or of the time objectified in him. He could repeat the work again and again, since he would have reproduced the value of the raw material and of the instrument as well as of the labouring capacity; the latter by constantly increasing the value of the former by 4 hours of objectified labour. But now let him receive the 40 thalers in wages only by working 8 hours, so that he would add to the material and instrument of labour, which now confront him as capital, a surplus value of 80 thalers; while the former surplus value of 40 thalers, which he added, is only exactly the value of his labour. He would thus add a surplus value exactly = to the surplus labour or surplus time. * The value of capital would thus have increased from 100 thalers to 140. †

* It is not in the least necessary at this point to assume that the material and instrument also has to increase along with surplus labour or surplus time. How surplus labour by itself increases the raw material, see Babbage, e.g. the working of gold wire etc. [54]

† Assume further that raw material doubles and the instrument of labour (for the sake

> of simpler arithmetic) increases by one-half. Then capital costs would amount to 100 thalers cotton, 20 thalers instrument, i.e. 120 thalers; for labour, now as then, 40 thalers; altogether 160 thalers. If a surplus labour of 4 hours increases 100 thalers by 40%, then it increases 160 thalers by 64 thalers. Hence the total product = 224 thalers. We here have presupposed, further, that the rate of profit does not vary with the size of capital; and material and instrument of labour are not regarded as being themselves realizations, capitalizations of surplus labour; as we saw, the greater the already posited surplus time, i.e. the size of capital as such, the more is it presupposed that an *absolute increase of labour time* is impossible, and that a relative increase, resulting from an increase in the productive force, declines in geometric proportion.

Now, capital regarded as simple exchange value would be absolutely greater, 140 thalers instead of 100; but in fact, a new value would merely have been created, i.e. a value which is not merely necessary to replace the 60 thalers in advances for the materials and the instrument of labour and the 40 thalers for labour, a new value of 40 thalers. The values in circulation would have been increased by 80 thalers, by 40 thalers of additional objectified labour time.

Now assume the same presupposition. 100 thalers capital; specifically, 50 for cotton, 40 for labour, 10 for instrument of production; let the surplus labour time remain as before, i.e. 4 hours, and the total labour time 8 hours. Thus in all cases the product only = 8 hours labour time = 140 thalers. Now suppose the productive force of labour doubles; i.e. 2 hours would be enough for the worker to realize raw materials and instrument to the extent required to maintain his labouring capacity. If 40 thalers were an objectified labour time of 4 hours, then 20 thalers would be the objectified labour time of 2 hours. These 20 thalers now express the same use value as the 40 thalers before. The exchange value of labouring capacity has diminished by half, because half of the original labour time creates the same use value, while the exchange value of the use value is measured purely by the labour time objectified in it. But the capitalist makes the workers work 8 hours now as before, and his product therefore represents now as before a labour time of 8 hours = 80 thalers of labour time, while the value of raw material and material remain the same, namely 60 thalers; altogether, as before, 140 thalers. (In order to live, the worker himself would have had to add to the 60 thalers of raw material and instrument a value of no more than 20 thalers, he would thus have created a value of only 80 thalers. The total value of his product would have diminished, by the doubling of production, from 100 to 80, by 20 thalers, i.e. by 1/5 of 100 = 20%.) But the surplus time or surplus value for capital is now 6 hours instead of 4, or 60 thalers instead of 40. Its increment is 2 hours, 20 thalers. His accounts would now show the following: for raw material, 50; for labour, 20; for instrument, 10; costs = 80 thalers. Gain = 60 thalers. Now as before he would sell the product for 140 thalers, but would show a gain of 60 thalers instead of 40 as before. On one side, therefore, he throws only the same exchange value into circulation as before, 140 thalers. But the surplus value of his capital has grown by 20 thalers. Accordingly, only the share he gets of the 140 thalers [is] the rate of his profit. The worker in fact worked 2 hours more for him free of charge, i.e. 6 hours instead of 4, and this is the same for him as if he had worked 10 hours instead of 8 in the earlier relation, had increased his *absolute labour time*. But indeed a *new value* has arisen also; namely 20 additional thalers are posited as *autonomous* value, as objectified labour which has become free, unbound from the task of serving only in exchange for earlier labour power [*Arbeitskraft*]. This can present itself in two ways. Either the 20 thalers set as much additional labour into motion as becomes *capital* and creates larger exchange value: make more objectified labour into the point of departure for the new production process; or the capitalist exchanges the 20 thalers as money for commodities other than those which he needs in its production as industrial capital; all commodities other than labour and money themselves thus are exchanged for 20 more thalers, for 2 more hours of objectified labour time. Their *exchange value* has thus increased by just this *liberated sum*. In fact, 140 thalers are 140 thalers, as the very ‘perceptive’ French publisher of the Physiocrats remarks against Boisguillebert. [55] But it is false that these 140 thalers only represent more use value; they represent a greater amount of *independent exchange value,* of *money*, of *latent capital*; i.e. of wealth posited as *wealth*. The economists themselves admit this later when they allow the accumulation of capitals to accumulate not only the mass of use values, but that of *exchange values* too; for, according to Ricardo himself, the element of the accumulation of capitals is posited just as completely with relative surplus labour as with absolute – impossible any other way. [56] On the other side, it is already implicit in the thesis best developed by Ricardo, that these excess 20 thalers, which are created purely by the increase in productive force, can become capital again.

Earlier, only 40 of the 140 thalers (leaving capital's consumption aside for now) could become new capital; 100 do not become capital but remain capital; now 60 [can], i.e. the present capital is greater by an exchange value of 20 thalers. Thus, exchange value, *wealth as such*, has increased, although the total sum of the same has not directly increased. Why has it increased? Because that part of the total sum has increased which was not a mere medium of circulation, but money; or which was not merely equivalent, but *exchange value for-itself* [*für sich seiend*]. Either the liberated 20 thalers were accumulated as money, i.e. added to the stock of exchange values in general (abstract) exchange value form; or they all circulated, and then the prices of the commodities bought with them rise; they all represent more money, as well as, since the production cost of gold has not fallen (rather, risen relative to the commodity produced by the more productive capital), more objectified labour (because of this, the excess production, which at first only appeared on the side of the one producing capital, now appears on the side of the others, which produce the more expensive commodities); or the 20 thalers are directly used up as capital by the originally circulating capital. Thus a new capital of 20 thalers is posited – a sum of self-preserving and self-realizing wealth. Capital has risen by the exchange value of 20 thalers. (Circulation actually does not yet concern us here, since we are here dealing with capital in general, and circulation can only mediate between capital in the form of money and capital in its form as capital; the first capital may realize money as such, i.e. exchange it for commodities, consume more than before; but in the hand of the producer of these commodities this money becomes capital. Thus it becomes capital directly in the hands of the first capital, or, via a detour, [in those] of another capital. But the other capital is always in turn capital as such; and we are concerned here with *capital as such*, [let us] say the capital of the whole society. The differentiation etc. of capitals does not concern us yet.) In general, these 20 thalers can appear only in a double form. As money, so that capital again exists in the character of money which has not yet become capital – its point of departure; the abstract-autonomous form of exchange value or of general wealth; or itself in turn as capital, as a new domination of objectified labour over living labour. * (Every increase in the mass of capital employed can increase the *productive force* not only at an arithmetical but at a geometrical rate; although it can increase profit at the same time – as increase of productive force – only at a much lower rate. The influence of the increase of capital on the increase of productive force is thus infinitely greater than that of the increase of the productive force on the growth of capital.) As general wealth, materialized in the form of money (of the thing, in its mere abstractness), or of *new* living labour. The capitalist consumes, say, 20 of the 140 thalers as use values for himself, through the mediation of money as means of circulation. Thus, in the first presupposition, he could begin the process of self-realization only with a larger capital, a larger use value of 120 (as against 100). After the doubling in the productive forces, he can do it with 140 thalers without restricting his consumption. A larger part of the exchange values solidifies as exchange value, instead of vanishing in use value (whether it solidifies as such, through production, directly or indirectly). To create a larger capital means to create a larger exchange value; although exchange value in its *direct form* as simple exchange value has not been increased by the growth of productivity, it has in its intensified form as *capital*. This larger capital of 140 thalers represents, absolutely, more objectified labour than the earlier capital of 120 thalers. It therefore also, at least relatively, sets more living labour into motion and therefore also ultimately reproduces more simple exchange value. The capital of 120 thalers at 40% produced a product or simple exchange value of 60 thalers at 40%; the capital of 140 thalers a simple exchange value of 64 thalers. Here, then, the increase in exchange value in the form of capital is still posited directly as an increase in exchange value in its simple form. It is of the highest importance to remember this. It is not enough to say, like Ricardo, that exchange value does not increase; i.e. the abstract form of wealth; but only exchange value as capital. [57] In saying this he is looking only at the original production process. But if relative surplus labour increases – and capital therefore increases absolutely – then there is necessarily also an increase within circulation also of *relative exchange value existing as exchange value*, money as such, and therefore, through the mediation of the production process, *absolute exchange value*. In other words, of this same amount of exchange value – or money – and the product of the realization process appears in this simple form – the product is surplus value only relative to capital, to value such as it existed before the production process; for itself, regarded as an independent existence, it is merely *quantitatively defined* *exchange value* – a part has become liberated, which does not exist as equivalent for already present exchange values or for already present labour time. If it is exchanged for those already present, it gives them not an equivalent but more than an equivalent, and thus liberates a part of the exchange value on their side. In a static state, this liberated exchange value by which society has become richer can only be money, in which case only the abstract form of wealth has increased; [is] in motion: [it] can realize itself only in *new* living labour (whether labour which had been dormant is set into motion, or *new workers* are created (population [growth] is accelerated) or again a new circle of exchange values, of exchange values in circulation, is expanded, which can occur on the production side if the liberated exchange value opens up a *new branch of production*, i.e. a new object of exchange, objectified labour in the form of a new use value; or the same is achieved when objectified labour is put in the sphere of circulation in a new country, by an expansion of trade). The latter must then be created.

* In the example given, the productive force has doubled, risen by 100%, the value of capital has risen by 20%.

The form in which Ricardo attempts to clarify the matter for himself (and he is very unclear in this regard) says at bottom nothing more than that he just introduces a certain relation, instead of saying, simply, that out of the same sum of simple exchange values a smaller part posits itself in the form of simple exchange value (equivalent) and a larger part in the form of money (money as the original, antediluvian form out of which capital always arises anew; money in its character as money, not as coin etc.); that therefore the part posited *as* exchange value for-itself, i.e. as *value*, increases, i.e. *wealth in the form of wealth* (whereas he comes to just the mistaken conclusion that it increases only in the form of material, physical wealth as use value). The origin of *wealth as such*, in so far as it arises not from *rent*, i.e., according to him, not from the *increase* in productive force, but rather from the *decrease of the same*, is therefore *totally incomprehensible* to him, and he entangles himself in the wildest contradictions. Let us take the form of the matter. [58] Capital 1,000 sets 50 workers into motion; or 50 living work days; through a doubling of the productive force, it could set 100 working days into motion. But these latter do not exist in the presupposition, and are introduced arbitrarily, because otherwise – unless *more real working days* are introduced – he does not grasp the increase in exchange value which arises from increased productivity. At the same time, the *growth of population* is never *developed* by him as an *element in the increase* of exchange values; never clearly and definitely stated. Let the presupposition be capital 1,000 and workers 50. The correct deduction, which he himself *also draws* (see Notebook) [59] : capital 500 with 25 workers can produce the same use value as before; the other 500 with the other 25 workers establish a new business and likewise produce an exchange value of 500. The profit remains the same, since it arises not from the exchange of 500 for 500, but from the proportions in which profit and wages originally divide in the 500, and since exchange deals in equivalents, which can no more increase value than *external trade* can, which Ricardo explicitly demonstrates. Since the exchange of equivalents just means nothing more than that the value in the hands of *A* before the exchange with *B* still exists in his hands after the exchange with *B*. The total value or wealth has remained the same. Use value, however, or the *material of wealth*, has doubled. Now, there is absolutely no reason here why *wealth* should grow as *wealth, exchange value as such* – as far as the *increase in the productive forces* is concerned. If the productive forces again double in both branches, then capital *A* can again divide into two of 250 with 12 1/2 working days each, capital *B* can do the same. [60] There are now four capitals with the same total exchange value of £1,000, consuming 50 living work days as before, [*] producing four times as much use value as before the doubling of consumption value. Ricardo is too classical to commit absurdities, like those who claim to improve on him, who derive the larger value after the increase in productive force from one party selling at a higher price within circulation. As soon as the capital of 500 has become commodity, simple exchange value, instead of exchanging it for 500, he exchanges it for 550 (at 10%), but then the other party obviously only gets 450 in exchange value instead of 500 and the total sum remains 1,000 as before. This happens often enough in commerce, but explains the profit made by one capital only by the loss of the other capital, and not *the* profit of *capital*; and without this presupposition there can be profit neither on one nor on the other side. Ricardo's process can therefore go on without any other limit than the *increase* *of the productive force* (and this is again physical, located outside the *economic relation* itself) possible with a capital of 1,000 and 50 workers. See the following passage: 'Capital is that part of the wealth of a country which is employed with a view to future production, *and may be increased in the same manner as wealth*.' [61] (*Wealth* for him the abundance of use values; and, seen from the standpoint of simple exchange, the identical objectified labour can express itself in limitless use values and constantly remain *the same exchange value*, as long as it remains the same amount of objectified labour, for its *equivalent* is measured not by the mass of use value in which it exists, but rather by its own amount.) 'An *additional capital* will be equally efficacious in the formation of future wealth, whether it be obtained from improvements of skill or machinery, or from using more revenue productively; for wealth' (use value) 'always depends on the *quantity* of commodities produced' (also somewhat on their variety, it seems), 'without regard to the facility with which the instruments employed in production may have been produced' (i.e. the labour time objectified in them). 'A certain quantity of clothes and provisions will maintain and employ the same number of men; but they will be of twice the value' (*exchange value*) 'if 200 have been employed on their production.' If, owing to an increase in the productive force, 100 produce as much in use values as 200 earlier, then: 'of the 200, half are let go, so that the remaining 100 produce as much as the 200 did before. Thus a half of the capital can be withdrawn from this branch of business; as much capital has become free as labour. And since one half of the capital now does quite the same service as did the whole, two capitals have now been formed etc.' (cf. 39, 40 ibid. on national trade, [62] to which we must return). Ricardo does not speak here about the working day; [the fact] that, if the capitalist earlier exchanged half of an objectified working day for the worker's entire living work day, [he] thus at bottom gains only half a living work day, since he gives the other half in objectified form to the worker, and obtains it from him in the living form, i.e. pays the worker a half of the working day, instead of in the form of simultaneous working days, i.e. of different workers; this does not alter the matter, only its expression. Each one of these working days furnishes so much more surplus time. If the capitalist, before, had *the* working day as limit, he now has 50 working days etc. As has been said, this form does not posit an increase in exchange values with an increase in the number of capitals through productivity, and, according to Ricardo, it would also be possible for the population to fall from, say, 10,000,000 to 10,000, without a decrease in exchange values or the quantity of use values (see conclusion of his book). [63] We are the last to deny that *capital* contains contradictions. Our purpose, rather, is to develop them fully. But Ricardo *does not develop them*, but rather shifts them off by considering the value in exchange as indifferent for the formation of wealth. That is to say, he contends that in a society based upon the value of exchange, and wealth resulting from such value, the contradictions to which this form of wealth is driven with the development of productive powers etc. do not exist, and that a progress of value is not necessary in such a society to secure the progress of wealth, consequently that value as the form of wealth does not at all affect that wealth itself and its development, i.e. he regards exchange value as merely *formal*. Then, however, he remembers (1) that the capitalists are concerned with value, (2) that, historically, with the progress of the productive forces (of international trade too, he *should have* noted), there is a growth in *wealth as such,* i.e. the sum of values. Now, how to explain this? Capitals accumulate faster than the population; thus wages rise; thus population; thus grain prices; thus the difficulty of production and hence the *exchange values*. The latter are then finally reached by a detour. We will here entirely omit the moment of rent, since we are not yet concerned with increased difficulty of production but rather with its opposite, with increase in the productive forces. With the accumulation of capitals, wages rise unless population grows simultaneously; the worker marries, production is spurred on or his children live better, do not die before their time etc. In short, the population grows. Its growth, however, gives rise to competition among the workers, and thereby forces the worker to sell his labour power to the capitalist at its *value* again, or momentarily even below it. Now the accumulated capital, which has meanwhile grown up more slowly, again has the surplus which it earlier spent in the form of wages, i.e. as coin, in order to buy the use value of labour, available to it in the form of money, in order to realize it as capital in living labour, and, since it now also disposes over a greater amount of working days, its *exchange value* grows in turn. (Even this not really developed in Ricardo, but mixed up with the theory of rent; since the surplus which capital earlier lost in the form of wages is now lost to it in the form of rent, owing to the growth of population.) But even the growth of population is not really comprehensible in his theory. At no time has he shown that there is an *inherent* relation between the whole of the labour objectified in capital and the living work day (whether the latter is represented as one working day of 50 × 12 hours, or as 12 hours of labour by 50 workers, is the same thing as far as the relation goes), and that this inherent relation is just the *relation between the fractional part of the living work day,* or that between the equivalent of the objectified labour with which the worker is paid, and the living working day; where the whole is the day itself, and the inherent relation is the variable relation (the day itself is a constant) between the *fractional part of the necessary hours of labour* and the *hours of surplus labour*. And, just because he has not developed this relation, he has also not developed [the point] (which did not concern us up to now, since we were concerned with *capital as such* and introduced the development of the productive forces as an external relation) that the development of the productive forces itself presupposes both the increase of capital and the increase of simultaneous working days, which, however, within the given barrier of a capital that sets one working day into motion (even if it be a day of 50 × 12 hours, 600 hours), is itself the barrier to the development of its productive force. The wage covers not only the worker, but also his reproduction; so that when this specimen of the working class dies, another replaces it; after the 50 workers are dead, 50 new ones are there to replace them. The 50 workers themselves – as living labour capacities – represent not only the costs of their own production, but also the costs which had to be paid to their parents above and beyond their wages as individuals, in order to replace themselves with 50 new individuals. Thus the population progresses even without a rise in wages. But now, why does it not progress rapidly enough? and why does it need a special stimulus? Surely only because the aim of capital is not served merely by obtaining more ‘wealth’ in the Ricardian sense, but because it wants more *value*, to command more objectified labour. But indeed, according to him, it can command the latter only if wages fall; i.e. if more living work days are exchanged for the same capital with objectified labour, and hence a greater value is created. In order to make wages fall, he presupposes increase of population. And in order to prove increase of population here, he presupposes that the demand for working days increases, in other words, that capital can buy more *objectified labour* (objectified in labouring capacity), hence that its *value* has grown. Originally, however, he proceeded from just the contrary presupposition, and took the detour only *because* that is where he began. If £1,000 was able to buy 500 working days, and the productive force increases, then either it can proceed to employ the 500 in the same branch of work, or it can divide up and employ 250 in one branch of work, 250 in another, so that this capital splits into 2 capitals of 500 each. But it can never command more than 500 working days, since otherwise, according to Ricardo, not only the use values it produces but also their *exchange value* must have multiplied itself, the *objectified labour time* over which it exercises command. Thus, given his presupposition, an increased demand for labour cannot take place. But if it does take place, then capital's *exchange value* has grown. Compare *Malthus on value*, who *senses* the contradictions, but falls flat when he himself tries to develop them. [64]

> * It is *at bottom false to say* that living labour consumes capital; capital (objectified labour) consumes the living in the production process.

Labour does not* reproduce *the value of the material in which, and of the instrument with which, it works. It* preserves *their value simply by relating to them in the labour process as to their objective conditions. This animating and preserving force costs capital* nothing; *appears, rather, as its own force etc.

We have always spoken only about the two elements of capital, the two parts of the living work day, of which one represents wages, the other profit; one, necessary labour, the other, surplus labour. But what about the other two parts of capital, which are realized in the material of labour and the instrument of labour? As far as the simple production process is concerned, labour presupposes the existence of an instrument which facilitates the work, and of a material in which it presents itself, which it forms. This form gives it its use value. This use value becomes exchange value through exchange, to the extent that it contains objectified labour. But are they, as components of capital, values which labour must replace? Thus in the above example (and such objections [were] heaped on Ricardo; that he regarded profit and wages only as components of production costs, not the machine and the material), it seems that if the capital is 100, divided 50 for cotton, 40 for wages, 10 for instrument; and if the wages, of 40 thalers, = 4 hours of objectified labour, and capital orders a working day of 8 hours, then the worker who has to reproduce 40 thalers for wages, 40 thalers surplus time (profit), 10 thalers instrument, 50 thalers cotton = 140 thalers, reproduces only 80 thalers. For 40 thalers are the product of half a working day; 40 are the other, surplus half. But the value of the two other component parts of capital is 60 thalers. Since the worker's real product is 80 thalers, he can reproduce only 80, not 140. He would have, instead, decreased the value of the 60; since 40 of the 80 [is] replacement for his wages; and the remaining 40 of surplus labour [is] smaller by 20 than 60. Instead of a profit of 40, the capitalist would have a loss of 20 on the part of his original capital consisting of instrument and material. How is the worker supposed to create still another 60 on top of the 80 thalers of value, since one half of his working day, as his wages show, creates only 40 thalers out of the instrument and the material; the other half only the same; and he disposes of only one working day, cannot work two days in one? Suppose the 50 thalers in material = x lb. of cotton yarn; the 10 thalers in instrument = spindle. Now, first, as regards the *use value*, it is clear that if the cotton did not already have the form of yarn and wood and iron the form of the spindle, then the worker could produce no *fabric*, no higher use value. For him himself, the 50 thalers and the 10 thalers in the production process are *nothing but yarn and spindle, not exchange values*. His labour has given them a higher use value, and added objectified labour to the amount of 80 thalers to them, i.e. 40 thalers to reproduce his wages, 40 surplus time. The use value – the fabric – contains one additional working day, half of which, however, replaces only that part of capital for which the disposition over the labouring capacity has been exchanged. The worker has not created the objectified labour contained in yarn and spindle, which form a part of the value of the product; for him they were and remain material to which he gave another form and into which he incorporated new labour. The only condition is that he should not waste them, and this he did not do, in so far as his product has use value, and a higher use value than before. It now contains objectified labour in two parts – his working day, and that already contained in his material, yarn and spindle, independent of him and before him. The previously objectified labour was the condition of *his* labour; it was necessary to make his labour what it is, costs him no labour. Suppose they were not already presupposed as components of capital, as *values*, and had cost *him* nothing. Then the value of the product, if he worked a whole day, would be 80, if a half day, 40 thalers. It would just = one objectified working day. Indeed, they cost him nothing in production; however, this does not destroy the labour time objectified in them, which remains and merely obtains another form. If, in addition to the fabric, the worker also had to create the yarn and the spindle in the same working day, then the process would be in fact impossible. The fact, therefore, that they call for his labour neither as use values in their original form, nor as exchange values, but are *on hand,* makes it possible for the addition of a working day by him to create a product of a value higher than one working day. He succeeds in this, however, to the extent that he does not have to create this additional part, but rather *finds it on hand* as material, as presupposition. It can therefore only be said that he reproduces these values in so far as *without* labour they would rot, be useless; but *without them, labour* would be equally useless. In so far as the worker reproduces these values, he does so not by giving them a higher exchange value, or entering into any process with their exchange value at all, but merely by subordinating them to the simple production process, merely by *working*. But this costs him no additional labour time *besides* what he needs for their processing and higher realization. It is a situation into which capital has put him so that he may work. He reproduces the values only by giving them a higher value, and this giving of a higher value is = his working day. Otherwise he lets them be as they are. That their old value is preserved happens because a new one is added to them, not that the old is itself *reproduced*, created. In so far as they are products of previous labour, a product of previous labour, a sum of previously objectified labour remains an element of his *product*, so that the product contains, in addition to its new value, the old as well. He therefore in fact produces in this product only the day's work which he adds to it, and the preservation of the old value costs him absolutely nothing apart from what it costs him to add the new. For him it is only a material, and remains that no matter how it changes its form; therefore [it is] something present *independently* of his labour. That this material, which remains that, since it only obtains a different form, itself already contains labour time is the business of capital, not his own; similarly, it is *independent* of his labour and continues on *after* it, just as it existed before it. This so-called reproduction costs him no labour time, but is rather the condition of his labour time, since it is nothing more than positing the substance on hand as the material of his labour, relating to it as material. He therefore replaces the old labour time by the *act* of working itself, not by the addition of special labour time for this purpose. He replaces it simply by the addition of the *new*, by means of which the old is preserved in the product and becomes an element of a new product. Thus the worker in his working day does not replace the raw material and the instrument in so far as they are values. *The capitalist thus obtains this preservation of the old value just as free of charge as he obtains surplus labour.* But he obtains it free of charge, because it costs the worker nothing, and is, instead, the result of the fact that the material and the instrument of labour are already in his hands as *presupposition*, and the worker cannot *work*, therefore, without making this already objectified labour, now in the hands of capital, into the material of his own labour, thereby also preserving the labour objectified in this material. The capitalist, then, pays the worker nothing for the fact that the yarn and the spindle – their value – reappear, as far as their value is concerned, in the fabric, and are thus preserved. This preservation takes place simply by the addition of new labour, which adds a higher value. What arises from the original relation between capital and labour, then, is that the same service which living labour as living labour performs for objectified labour costs capital nothing, just as it costs the worker nothing, but merely expresses the relation that the material and the instrument of labour confront the worker as capital, as presuppositions *independent* of him. The preservation of the old value is not a separate act from the addition of the new, but happens by itself; appears as a natural result of the same. But the fact that this preservation costs capital nothing and costs the worker nothing either is already posited in the relation of *capital and labour*, which in itself is already the former’s profit and the latter’s wage.

The individual capitalist may imagine (and for his accounts it serves as well) that, if he owns a capital of 100 thalers, 50 thalers in cotton, 40 thalers to buy labour with, 10 thalers in instrument, plus a profit of 10% counted as part of his production costs, then labour has to replace his 50 thalers of cotton, 40 thalers subsistence, 10 thalers instrument plus 10% of 50, of 40 and of 10; so that in his imagination, labour creates 55 thalers of raw material, 44 thalers subsistence and 11 thalers instrument for him, together = 110. But this is a peculiar notion for economists, even though it has been advanced with great pomp as an innovation against Ricardo. If the worker's working day = 10 hours, and if he can create 40 thalers in 8 hours, i.e. can create his wage, or, what is the same, can maintain and replace his labour capacity, then he needs 4/5 of a day in order to replace his wages for capital, and he gives capital 1/5 in surplus labour, or 10 thalers. In exchange for the 40 thalers in wages, for 8 hours of objectified labour, therefore, capital obtains 10 hours of living labour, and this excess constitutes the entirety of its profit. The total objectified labour which the worker has created, then, is 50 thalers, and, regardless of the costs of the instrument and of the raw materials, more he cannot add, for his day cannot objectify itself in more labour than that; now, the fact that he adds these 50 thalers – 10 hours of labour (of which only 8 replace the wage) – to the 60 thalers contained in raw material and instrument – and thereby has simultaneously preserved the raw material and the instrument – they are preserved just by coming into contact again with living labour, and being used as instrument and as material – this costs him no labour (and he would have no time available in which to do this), nor does the capitalist pay him for it. Like every other natural or social power of labour unless it is the product of previous labour, or of such previous labour as does not need to be repeated (e.g. the historical development of the worker etc.), this natural animating power of labour – namely that, by using the material and instrument, it preserves them in one or another form, including the labour objectified in them, their exchange value – becomes a *power of capital*, not of labour. Hence not paid for by capital. As little as the worker is paid for the fact that he can think etc.

We have seen the original presupposition of the coming into being of *capital* is the existence of *money as money*, i.e. as money which has withdrawn from circulation and asserts itself *negatively* towards it, i.e. *value* which has become independent from and *against* circulation – i.e. the commodity for which the character of exchange value is not merely a formal, vanishing character, [which it possesses only] before being exchanged for another use value and finally disappearing as an object of consumption. On the other side, *money* (in its third, adequate form) – as value which no longer enters circulation as equivalent, but is not yet potentiated as capital, i.e. value independent of and relating *negatively* against circulation – is at the same time the result of capital's product, in so far as that product is not merely its own *reproduction* (but this reproduction is merely formal, since, of the three parts of its value, only one is really consumed and hence reproduced, namely that which replaces wages; profit, on the other hand, is not reproduction but addition of value, surplus value). Just as money at first appeared as the presupposition, the cause of capital, so it now appears as its effect. In the first movement, money arose out of simple circulation; in the second it arises from the production process of capital. In the first, it *makes a transition to* capital; in the second it appears as a presupposition of capital posited by capital itself; and is therefore already posited as capital *in itself* [*an sich*], already contains the ideal relation towards capital. It does not simply make a transition to capital, but rather, as *money,* its potential to be transformed into capital is already posited in it.

Absolute surplus labour time. Relative. – It is not the* quantity *of living labour, but rather its* quality *as labour which simultaneously preserves the labour time already contained in the material etc. – The change of form and substance in the direct production process. – The preservation of the previous stage of production by the subsequent one is contained in the simple production process etc. – Preservation of the old use value by new labour etc. – Process of production and process of realization. The* quantity *of objectified labour is preserved because contact with living labour preserves its quality as use value for new labour. – In the real production process, the separation of labour from its objective conditions of existence is suspended. But in this process labour already incorporated in capital etc. Appears as capital's power of self-preservation. Eternalization of value

The increase of values is therefore the result of the self-realization of capital; [regardless of] whether this self-realization is the result of *absolute* surplus time or of *relative*, i.e. of a real increase in absolute labour time or of an increase in relative surplus labour, i.e. of a decrease in the fractional part of the working day which is required as labour time necessary to preserve the labouring capacity, as *necessary labour* in general.

Living labour time reproduces nothing more than that part of objectified labour time (of capital) which appears as an equivalent for the power of disposition over living labour capacity, and which, therefore, as an equivalent, must replace the labour time objectified in this labouring capacity, i.e. replace the production costs of the living labour capacities, in other words, must keep the workers alive as workers. What it produces in addition to that is not reproduction but rather new creation, and, more specifically, creation of new values, because it is the objectification of new labour time in a use value. That the labour time contained in the raw material and instrument is preserved at the same time is a result *not of the quantity of labour*, but of its *quality* of being labour as such; and there is no special payment for this, its general quality, for the fact that *labour, as labour, is labour* – leaving aside all special qualifications, all specific kinds of labour – because capital has bought *this quality* as part of its exchange with the worker.

But the equivalent for this quality (for the specific use value of labour) is measured simply by the *quantity* of labour time which has produced it. Initially the worker’s use of the instrument as an instrument, and his shaping of the raw material, adds to the value of the raw material and of the instrument as much new form as is = to the labour time contained in his own wage; what he adds additionally is surplus labour time, surplus value. For their part, the raw materials and the instrument are preserved not in their form but in their substance, through the simple relation of being used as instrument and being posited as the raw material of labour, the simple process of coming into contact with labour, being posited as its means and object and therefore as objectification of living labour, moments of labour itself; and, viewed economically, their substance is objectified labour time. By being posited as a material mode of existence – means and end [*Objekt*] – of living labour, objectified labour time ceases to exist in a one-sided, objective form, in which, as a mere thing, it is at the prey of processes of chemical decay etc. There is an indifference on the part of the substance [*Stoff*] towards the form, which develops out of merely objectified labour time, in whose objective existence labour has become merely the vanished, *external form* of its natural substance, existing merely in the external form of the substantial [*das Stoffliche*] (e.g. the form of the table for wood, or the form of the cylinder for iron); [65] no immanent law of reproduction maintains this form in the way in which the tree, for example, maintains its form as a tree (wood maintains itself in the specific form of the tree because this form is a form of the wood; while the form of the table is accidental for wood, and not the intrinsic form of its substance); it exists only as a form external to the substance, or it exists only as a substance [*stofflich*]. The dissolution to which its substance is prey therefore dissolves the form as well. However, when they are posited as conditions of living labour, they are themselves reanimated. Objectified labour ceases to exist in a dead state as an external, indifferent form on the substance, because it is itself again posited as a moment of living labour; as a relation of living labour to itself in an objective material, as the *objectivity* of living labour (as means and end [*Objekt*]) (the *objective* conditions of living labour). The transformation of the material by living labour, by the realization of living labour in the material – a transformation which, as purpose, determines labour and is its purposeful activation (a transformation which does not only posit the form as external to the inanimate object, as a mere vanishing image of its material consistency) – thus preserves the material in a definite form, and subjugates the transformation of the material to the purpose of labour. Labour is the living, form-giving fire; it is the transitoriness of things, their temporality, as their formation by living time. In the simple production process – leaving aside the realization process – the transitoriness of the forms of things is used to posit their usefulness. When cotton becomes yarn, yarn becomes fabric, fabric becomes printed etc. or dyed etc. fabric, and this becomes, say, a garment, then (1) the substance of cotton has preserved itself in all these forms. (The chemical process, regulated by labour, has everywhere consisted of an exchange of (natural) equivalents etc.); (2) in each of these subsequent processes, the material has obtained a more useful form, a form making it more appropriate to consumption; until it has obtained at the end the form in which it can directly become an object of consumption, when, therefore, the consumption of the material and the suspension of its form satisfies a human need, and its transformation is the same as its use. The substance of cotton preserves itself in all of these processes; it becomes extinct in one form of use value in order to *make way for a higher one, until the object is in being as an object of direct consumption*. But when cotton is posited, say, as twist, then it is posited in a specific relation to a further kind of labour. If this labour were not to take place, then not only has the form been posited in it uselessly, i.e. the previous labour is not reaffirmed by new labour, but the material is also spoiled, because, in the form of twist, it has a use value only in so far as it is worked on further: it is a use value only in respect of the use which further labour makes of it; is use value only in so far as its form as twist is suspended in the form of fabric; while cotton in its existence as cotton is capable of an infinite number of useful employments. Thus, without further labour, the use value of cotton and twist, material and form, would be botched; it would be destroyed instead of produced. Material as well as form, substance like form, are preserved by further labour – preserved as use value, until they obtain the form of use value as such, whose use is consumption. It is therefore already a part of the simple production process that the earlier stage of production is preserved by the later, and that positing the higher use value preserves the old, or, the old use value is transformed only to the extent that it is raised to a higher use value. It is living labour which preserves the use value of the incomplete product of labour by making it the material of further labour. It preserves it, however, i.e. protects it from uselessness and decay, only by working it in a purposeful way, by making it the object of new living labour. *This preservation of the old use value* is not a process taking place separately from the increase or the completion of the use value by new labour; it takes place, rather, entirely in this new labour of raising the use value. When the labour of weaving transforms yarn into fabric, i.e. treats yarn as the raw material of weaving (a particular form of living labour) (and twist has a use value only if it is woven into fabric), it thereby preserves the use value which cotton had as such, as well as that which cotton had obtained specifically as yarn. It preserves the product of labour by making it into the raw material of new labour; but what happens is not that it (1) adds new labour and (2) besides that, by means of additional labour, preserves the use value of the raw material. *It preserves the utility of cotton as yarn by weaving the yarn into fabric.* (All this belongs already in the first chapter *on production in general.*) *Preserves it by weaving it.* This preservation of labour as product – of the use value of the product of labour by its becoming the raw material of new labour, being again posited as material objectivity of purposeful living labour – is given with the simple production process. As regards use value, labour has the property of preserving the existing use value by raising it, and it raises it by making it into the object of new labour as defined by an ultimate aim; by changing it in turn from the form of its indifferent consistency into that of objective material, the body of labour. (*The same holds for the instrument.* A spindle maintains itself as a use value only by being used up for spinning. If it is not, the specific form which is here posited in iron and wood would be spoiled for use, together with the labour which posited it and the material in which it did the positing. The use value of wood and iron, and of their form as well, are preserved only by being posited as a means of living labour, as an objective moment of the existence of labour's vitality. As an instrument of labour, it is their destiny [*Bestimmung*] to be used up, but used up in the process of spinning. The increased productivity which it lends to labour creates more use values and thereby replaces the use value eaten up in the consumption of the instrument. This appears most clearly in agriculture, because there the instrument appears most easily, because most anciently, as a use value, directly as a means of life – in contrast to exchange value. If the hoe allows the tiller to grow twice as much grain as before, then he has to spend less time on the production of the hoe itself; he has enough food to make a new hoe.) Now, in the realization process, the value components of capital – the one in the form of the material, the other in the form of instrument – confront the worker, i.e. living labour (for the labourer exists in the process only as such) not as values, but rather as simple moments of the production process; as use values for labour, as the objective conditions of its efficacity, or as its objective moments. It lies in the nature of labour itself to preserve them by using the instrument as instrument and by giving the raw material a higher form of use value. But, as components of capital, the use values thus obtained from labour are exchange values; as such, determined by the costs of production contained in them, the amount of labour objectified in them. (Use value is concerned only with the *quality* of the labour already objectified.) The quantity of *objectified labour* is preserved in that its *quality* is preserved as *use value for further labour*, through the contact with living labour. The use value of cotton, as well as its use value as yarn, are preserved by being woven; by existing as one of the objective moments (together with the spinning wheel) in the weaving process. *The quantity of labour time contained in the cotton and the cotton yarn are therefore also preserved thereby. The preservation of the quality of previous labour in the simple production process, – hence of its material* as well – becomes, in the realization process, the preservation of the quantity of labour already objectified. *For capital*, this preservation is the preservation of the amount of objectified labour *by* the production process; for *living labour* itself, it is merely the preservation of the already present use value. Living labour *adds a new amount of labour*; however, it is not this *quantitative addition* which preserves the amount of already objectified labour, but rather its *quality as living labour*, the fact that it relates as labour to the use values in which the previous labour exists. But living labour is not paid for this quality, which it possesses as living labour – if it were not living labour, it would not be bought at all – rather, it is paid for the *amount of labour* contained in itself. What is paid for is only the *price* of its use value, like that of all other commodities. It does not receive payment for its specific quality of adding new amounts of labour to the amounts of labour already objectified, and at the same time preserving labour which is already objectified as objectified labour; and this quality does not cost the worker anything either, since it is a natural property of his labouring capacity. Within the production process, the separation of labour from its objective moments of existence – instruments and material – is *suspended. The existence of capital and of wage labour rests on this separation. Capital does not pay for the suspension of this separation which proceeds in the real production process* – for otherwise work could not go on at all. (Nor does this suspension take place in the process of exchange with the worker; but rather *in the process of work itself, during production*. But, as *ongoing labour*, it is itself already incorporated in capital, and a moment of the same. This preserving force of labour therefore appears as the self-preserving force of capital. The worker has merely added new labour; as for previous labour –

owing to the existence of capital – this has an eternal existence as value, quite independent of its material existence. This is how the matter appears to capital and to the worker.) If it had to pay for this quality also, then it would just cease to be capital. This is part of the material role which labour plays by its nature in the production process; of its use value. But as use value, labour belongs to the capitalist; it belongs to the worker merely as exchange value. Its living quality of preserving objectified labour time by using it as the objective condition of living labour in the production process is none of the worker's business. *This appropriation, by means of which living labour makes instrument and material in the production process* into the body of its soul and thereby resurrects them from the dead, does indeed stand in antithesis to the fact that labour itself is objectless, is a reality only in the immediate vitality of the worker – and that the instrument and material, in capital, exist as beings-for-themselves [*für sich selbst seiende*]. (Return to this.) The process of the realization of capital proceeds by means of and within the simple production process, by putting living labour into its natural relation with its moments of material being. But to the extent that labour steps into this relation, this relation exists not for itself, but for capital; labour itself has become already a moment of capital.

Capitalist obtains surplus labour free of charge together with the maintenance of the value of material and instrument. Labour, by adding a new value to the old one, at the same time maintains, eternizes [sic] the latter. – The* preservation *of values in the product costs capital nothing. – By means of the appropriation of ongoing labour, the capitalist already possesses a claim to (and, respectively) appropriation of future labour

We see therefore that the capitalist, by means of the exchange process with the worker – by indeed paying the worker an equivalent for the costs of production contained in his labour capacity, i.e. giving him the means of maintaining his labour capacity, but appropriating living labour for himself – obtains two things free of charge, first the surplus labour which increases the value of his capital; but at the same time, secondly, the quality of living labour which maintains the previous labour materialized in the component parts of capital and thus preserves the previously existing value of capital. But this preservation does not take place as a result of an *increase in the amount of labour objectified* by living labour, a creation of value, but simply as a result of its existence as living *labour* in the proper relation with material and instrument, i.e. through its *quality* as living labour. As such a quality, it is itself a moment of the simple production process and does not cost the capitalist anything, any more than yarn and spindle do, apart from their price, for having also become moments of the production process.

When e.g. in times of stagnations of trade etc. the mills are shut down, then it can indeed be seen that the machinery rusts away and that the yarn is useless ballast and rots, as soon as their connection with living labour ceases. If the capitalist employs labour only in order to create surplus value – to create value in addition to that already present – then it can be seen as soon as he orders work to stop that his already present capital, as well, becomes devalued; that living labour hence not only adds new value, but, by the very act of adding a new value to the old one, maintains, eternizes it. (This shows clearly the absurdity of the charge against Ricardo, that he conceives *only* profits and wages as necessary components of the cost of production, and not also the part of capital contained in raw materials and instrument. To the extent that the value which they represent is merely preserved, there are no new production costs. But as far as these present values themselves are concerned, they all dissolve again into objectified labour – necessary labour and surplus labour – wages and profit. The purely natural material in which no human labour is objectified, to the extent that it is merely a material that exists independently of labour, has no *value*, since only objectified labour is value; as little value as is possessed by the common elements as such.) The maintenance of present capital by the labour which realizes it therefore costs capital nothing and hence does not belong among the production costs; although the present values are preserved in the product and equivalents have therefore to be given for them in exchange. But the *maintenance of these values* in the product costs capital nothing and cannot therefore be cited among the costs of production. Nor are they replaced by labour, since they are not consumed, except in so far as they are consumed apart from and outside labour, i.e. as labour *consumes* (suspends) their *transitoriness*. Only the wage is really consumed.

Let us return once more to our example. 100 thalers capital, i.e. 50 thalers raw material, 40 thalers labour, 10 thalers instrument of production. Let the worker require 4 hours in order to create the fraction of production necessary for his maintenance, the 40 thalers representing the means of his life. Let his working day be 8 hours. The capitalist then obtains a surplus of 4 hours free of charge; his surplus value equals 4 objectified hours, 40 thalers; hence his product = 50 + 10 (preserved, not reproduced values; remained *constant, unchanged* as values) + 40 thalers (wages, reproduced, because consumed in the form of wage) + 40 thalers of surplus value. *Sum*: 140 thalers. Of these 140, 40 are excess. The capitalist had to live during production and before he began to produce; say 20 thalers. He had to own the latter apart from his capital of 100 thalers; hence equivalents for them had to be present in circulation. (How these arose does not concern us here.) Capital presupposes circulation as a constant magnitude. These equivalents now present again. Thus consumes 20 thalers of his gain. These enter into simple circulation. The 100 thalers also enter into simple circulation, but only in order to be transformed again into the conditions of new production, 50 thalers of raw material, 40 subsistence for workers, 10 instrument. There remains a surplus value, an addition as such, newly created, of 20 thalers. This is *money*, posited as a negatively independent value against circulation. It cannot enter into circulation as a mere equivalent, in order to exchange for objects of mere consumption, since circulation is presupposed as constant. But the independent, illusory existence of money is suspended; it now only exists in order to be realized, i.e. to become capital. In order to become that, however, it would again have to be exchanged for the moments of the production process, subsistence for workers, raw material and instrument; all these dissolve into objectified labour, can only be posited by living labour. *Money*, then, in so far as it now already *in itself* exists as capital, is therefore simply *a claim on future* (new) labour. It exists, objectively, merely as *money*. Surplus value, the new growth of *objectified labour*, to the extent that it exists for itself, is *money*; but now, it is money which *in itself* is already capital; and, as such, it is a *claim on new labour*. Here capital already no longer enters into relation with ongoing labour, but with future labour. And it no longer appears dissolved into its simple elements in the production process, but as money; no longer, however, as money which is merely the abstract form of general wealth, but as a claim on the real possibility of general wealth – labour capacity, and more precisely, *labour capacity in the process of becoming* [*das werdende Arbeitsvermögen*]. As a claim, its material existence as money is irrelevant, and can be replaced by any other title. Like the creditor of the state, every capitalist with his newly gained value possesses a claim on future labour, and, by means of the appropriation of ongoing labour has already at the same time appropriated future labour. (This side of capital to be developed to this point. But already here its property of existing as value separately from its substance can be seen. This already lays the basis for credit.) To stockpile it in the form of money is therefore by no means the same as materially to stockpile the material conditions of labour. This is rather a stockpiling of property titles to labour. Posits future labour as *wage labour*, as use value for capital. No *equivalent* on hand for the newly created value; its possibility only in new labour.

In this example, then, an absolute surplus labour time of 4 hours created, added to the old values, to the world of available wealth, a new value of 20 thalers money, and money already in connection with its form as capital (already as *posited possibility* of capital, not as before, becoming the possibility of capital as such only by ceasing to be money as such).

Now if the productive force doubles, so that instead of 4 hours the worker has to put in only 2 hours of *necessary labour*, and if the capitalist makes him work 8 hours as before, then the accounts are as follows: 50 thalers material, 20 wages, 10 instrument of labour, 60 surplus value (6 hours, 4 before). New growth of absolute surplus value: 2 hours or 20 thalers. *Sum*: 140 thalers (in the product).

A total of 140 thalers as before; but now 60 of them are surplus value; of which 40 for absolute increase in surplus time as before, 20 for relative. But the simple exchange value only contains 140 thalers as before. Now, is it only the use values which have increased, or has a new value been created? Before, capital had to begin again with 100 in order to realize itself anew at 40%. What happens to the 20 of surplus value? Before, the capitalist ate up 20 of them; he was left with a value of 20. Now he eats up 20 and is left with 40. On another side, the capital entering into production remained 100; now it has become 80.

What is gained in value on one side in one form is lost as value on the other side in another form. The first capital re-enters into the production process; again produces a surplus value (capitalist's consumption deducted) of 20. At the end of this second operation, a newly created value is present without equivalent. 20 thalers together with the first 40. Now let us take the second capital.

Material, 50; wages (2 hours), 20; instrument, 10. But in the 2 hours he produces a value of 8, i.e. 80 thalers (of which 20 for costs of production). Remainder, 60, since 20 reproduce the wage (disappear as wage). 60 + 60 = 120. At the end of this second operation, 20 thalers for consumption; remainder surplus value 20; together with the first operation, 60. In the third operation with the first capital, 60; with the second, 80; in the fourth operation with the first capital 80, with the second, 100. The first capital has increased as *value* in proportion as its exchange value, as productive capital, has decreased.

Suppose both capitals together with their surplus can be used as capital; i.e. their surplus exchanged for new labour. We then get the following calculation (leaving consumption aside): the *first* capital produces 40%, the second 60%. 40% of 140 is 56; 60% of 140 (i.e. capital, 80; surplus value, 60) is 84. The total product in the first case 140 + 56 = 196; in the second 140 + 84 = 224. In the second case absolute surplus value 28 higher than in the first. The first capital has 40 thalers with which to buy new labour time; the value of the hour of labour was presupposed at 10 thalers; therefore, his 40 thalers buy 4 new hours of labour, which produce 80 for him (of which 40 go to replace the wages of 8 hours of labour). At the end it was 140 + 80 (i.e. reproduction of the capital of 100: surplus value of 40, or reproduction of 140; or, in the first case, 100 thalers reproduce themselves as 140; the second 40, since they are spent only to buy new labour, hence do not *simply* replace value – impossible presupposition, by the way) which produce 80. 140 + 80 = 220. The second capital of 140; the 80 produce 40; or the 80 thalers reproduce themselves as 120; the remaining 60, however, reproduce themselves (since they are spent *purely* for the purchase of *labour*, and do not therefore simply replace any value, but reproduce out of themselves and posit the surplus) as 180; then 120 + 120 = 240. (Produced 40 thalers more than the first capital, exactly the surplus time of two hours, for the first is a surplus time of 2 hours as assumed in the first case). Thus the result is a greater exchange value, because more labour objectified; 2 hours more surplus labour.

Something else should be noted here as well: 140 thalers at 40% yield 56; capital and interest together = 140 + 56 = 196; but we have obtained 220; according to which the interest on 140 would be not 56 but 84; which would be 60% on 140 (140:84 = 100:*x*; *x* = 8,400/140 = 60). Similarly in the second case: 140 at 60% = 84; capital and interest = 140 + 84 = 224; but we obtain 240; according to which the interest on the 140 is not 84 but 100; (140 + 100 = 240); i.e., %, (140:100 = 100:*x; x* = 10,000/140); [*x* = 71 3/7%]. Now where does this come from? (In the first case 60% instead of 40; in the second 71 3/7 instead of 60%.) In the first case, where it was 60 instead of 40, hence 20% too much came out; in the second case 71 3/7 instead of 60, i.e. 11 3/7 too much. Why, then, firstly the difference between the two cases and secondly the difference in each case?

In the first case, the original capital was 100 = 60 (material and instrument of labour) plus 40 in labour; 2/5 labour, 3/5 (material). The first 3/5 bring no interest at all; the last 2/5 bring 100%. But computed on the basis of the whole capital, the increase is only 40%; 2/5 of 100 = 40. But the 100% on the latter amount to only 40% on the whole 100; i.e. an increase of 2/5 in the whole. Now, if only 2/5 of the newly arrived capital of 40 had increased by 100%, then this would yield an increase of the whole by 16 [thalers]. 40 + 16 = 56. This together with the 140 = 196; which is then actually 40% on 156, capital and interest reckoned together. 40 increased by 100%, doubled, is 80; 2/5 of 40 increased by 100% is 16. [66] 40 of the 80 replace capital. Gain of 40.

The account then: 100*c* + 40 interest + 40*c* + 40*i* = 220; or, capital of 140 with an interest of 80; but if we had calculated 100*c* + 40*i* + 40*c* + 16*i* = 196; or, capital of 140 with interest of 56.

An interest of 24 on a capital of 40 is too much; but 24 = 3/5 of 40 (3 × 8 = 24); i.e. in addition to the capital, only 2/5 of the capital grew by 100%; the whole capital therefore by only 2/5, i.e. 16%. [67] The interest computation on 40 is 24% too high (by 100% on 3/5 of the capital); 24 on 24 is 100% on 3 × 8 (3/5 of 40). But on the whole amount of 140, it is 60% instead of 40; i.e. 24 too much out of 40, 24 out of 40 = 60%. Thus we figured 60% too much on a capital of 40 (60 = 3/5 of 100). But we figured 24 too high on 140 (and this is the difference between 220 and 196); this is first 1/5 of 100 then 1/12 of 100 too much; 1/5 of 100 = 20%; 1/12 of 100 = 8 4/12% or 8 1/3%; thus altogether 28 1/3% too high. Thus on the whole not 60%, as on 40, but only 28 1/3% too much; which makes a difference of 31 2/3, depending on whether we figure 24 too many on the 40 [or on] the capital of 140. Similarly in the other example.

In the first 80 which produce 120, 50 + 10 was simply replaced, but 20 reproduced itself threefold: 60 (20 reproduction, 40 surplus).

Hours of labour
If 20 posit 60, making up triple the value, then
60 180.

NOTEBOOK IV

Mid-December 1857 – 22 January, 1858

The Chapter on Capital (continuation)

Confusion of profit and surplus value. Carey's erroneous calculation. – The capitalist, who does **not pay** ***the worker for the*** **preservation** ***of the old value, then demands remuneration for giving the worker permission to preserve the old capital. – Surplus value and profit etc. – Difference between consumption of the instrument and of wages. The former consumed in the production process, the latter outside it. – Increase of surplus value and decrease in rate of profit. (Bastiat)***

This highly irksome calculation will not delay us further. The point is simply this: if, as in our first example, material and instrument amount to 3/5 (60 out of 100), and wages 2/5 (40), and if the capital yielded a gain of 40%, then it equals 140 at the end (this 40% gain equal to the fact that the capitalist made the workers put out 12 hours of labour, where 6 were necessary, hence gained 100% on the necessary labour time). Now if the 40 thalers which were gained go to work again as capital with the same presuppositions – and at the present point, the presuppositions have not changed yet – then of the 40 thalers 3/5 i.e. 24 thalers have to be used for material and instrument, and 2/5 for labour; so that the only thing that doubles is the wage of 16 which becomes 32, 16 for reproduction, 16 surplus labour; so that altogether at the end of production 40 + 16 = 56 or 40%. Thus the entire capital of 40 would have produced 196 under the same conditions. It should not be assumed, as happens in most of the economics books, that the 40 thalers are spent purely for wages, to buy living labour, and thus yield 80 thalers at the end of production.

<If it is said: a capital of 100 yields 10% in one period, 5% in another, then nothing is more mistaken than to conclude, as do Carey and consorts, that the share of capital in production was 1/10 and that of labour 9/10 in the first case; in the second case, the share of capital only 1/20 and that of labour 19/20; i.e. that the share of labour rises as the rate of profit falls. [1] From the viewpoint of capital – and capital has no awareness whatever of the nature of its process of realization, and has an interest in having an awareness of it only in times of *crisis* – a profit of 10% on a capital of 100 looks like a profit on each of its value

components – material, instrument, wages – equally and indifferently, as if this capital were simply a sum of 100 thalers of value which had, as such, increased by 10%. But the question is, in fact: (1) what was the relation between the component parts of capital and (2) how much surplus labour did it buy with the wage – with the hours of labour objectified in the wage? If I know the total size of a capital, the relation of its value components to one another (in practice, I would also have to know what part of the instrument of production is used up in the process, i.e. actually enters into it), and if I know the profit, then I know how much surplus labour has been created. If 3/5 of the capital consisted of material (which for the sake of convenience we here suppose to be entirely consumed productively as material of production), i.e. 60 thalers, and wages 40, and if the profit on the 100 thalers is 10, then the labour bought for 40 thalers of objectified labour time has created 50 thalers of objectified labour in the production process, hence has worked a surplus labour time or created a surplus value of 25% = 1/4 of the necessary labour time. Then if the worker works a day of 12 hours, he has worked 3 hours of surplus time, and the labour time necessary to maintain him alive for one day was 9 hours of labour. The new value created in production may only be 10 thalers, but, according to the real rate, these 10 thalers are to be reckoned on the base of the 40, not of the 100. The 60 thalers of value have created no value whatever; the working day has. Thus the worker has increased the part of capital spent for labour capacity by 25%, not by 10%. The total capital has grown by 10%. 10 is 25% of 40; it is only 10% of 100. Thus the profit rate on capital in no way expresses the rate at which living labour increases objective labour; for this increase is merely = to the surplus with which the worker reproduces his wage, i.e. = to the time which he works over and above that which he would have to work in order to reproduce his wages. If the worker in the above example were not a worker for a capitalist, and if he related to the use values contained in the 100 thalers not as to capital but simply as to the objective conditions of his labour, then, before beginning the production process anew, he would possess 40 thalers in subsistence, which he would consume during the working day, and 60 thalers in instrument and material. He would work only 3/4 of a day, 9 hours, and at the end of the day his product would be not 110 thalers but 100, which he would again exchange in the above proportions, beginning the process again and again. But he would also work 3 hours less; i.e. he would save 25% surplus labour = 25% surplus value out of the exchange which he undertakes between 40 thalers in subsistence and his labour time; and if at some time he worked 3 hours extra, because the material and the instrument were there on hand, then it would not occur to him to say that he had created a new value of 10%, but rather one of 25%, because he could buy one fourth additional subsistence, 50 thalers' worth instead of 40; and, since he is concerned with use values, these items of subsistence by themselves would be of value for him. This illusion that the new value is derived not from the exchange of 9 hours of labour time as objectified in 40 thalers for 12 hours of living labour, i.e. a surplus value of 25% on this part, but that it comes from an even 10% increase in the total capital – 10% of 60 is 6 and of 40 is 4 – this illusion is the basis of the notorious Dr Price's *compound interest calculation*, [2] which led the heaven-born Pitt to his *sinking fund* idiocy. [3] The identity of surplus gain with surplus labour time – absolute and relative – sets a qualitative limit on the accumulation of capital, namely the *working day*, the amount of time out of 24 hours during which labouring capacity can be active, the degree to which the productive forces are developed, and the population, which expresses the number of simultaneous working days etc. If, on the other side, surplus value is defined merely as interest – i.e. as the relation in which capital increases itself by means of some imaginary sleight of hand, then the limit is merely quantitative, and there is then absolutely no reason why capital cannot every other day convert the interest into capital and thus yield interest on its interest in infinite geometrical progression. Practice has shown the economists that Price's interest-multiplication is impossible; but they have never discovered the blunder contained in it.

Of the 110 thalers which emerge at the end of production, 60 thalers (material and instrument), in so far as they are values, have remained absolutely unchanged. The worker took nothing away from them and added nothing to them. Of course, from the standpoint of the capitalist, the fact that the worker maintains the value of objectified labour by the very fact of his labour being living labour appears as if the worker still had to pay the capitalist to get permission to enter into the proper relation with the objectified moments, the objective conditions, of labour. Now, as regards the remaining 50 thalers, 40 of them represent not only preservation but *actual reproduction*, since capital has divested itself of them [*von sich entäussert*] in the form of wages and the worker has consumed them; 10 thalers represent production above and beyond reproduction, i.e. 1/4 surplus labour (of 3 hours). Only these 50 thalers are a product of the production process. Therefore, if the worker, as is wrongly asserted, divided the product with the capitalist so that the former's share were 9/10, then he would have to get not 40 thalers (and he has obtained them in advance, in exchange for which he has reproduced them and paid them back in their entirety, as well as maintaining the already existing values for the capitalist free of charge), which is only 8/10 but rather 45, which would leave capital only 5. Then, having begun the production process with 100 thalers, the capitalist would have at the end only 65 thalers as product. But the worker obtains none of the 40 thalers he has reproduced, nor any of the 10 thalers of surplus value. If the 40 thalers which have been reproduced are to serve for the purchase of further living labour, then, as far as the relation is concerned, all that can be said is that an objectified labour of 9 hours (40 thalers) buys living labour for 12 hours (50 thalers) and thus yields a surplus value of 25% of the real product (partly reproduced as wage fund, partly newly produced as surplus value) in the realization process.

Just now the original capital of 100 was: 50 – 10 – 40. [4] Produced surplus gain of 10 thalers (25% surplus time). *Altogether* 110 thalers.

Now suppose it were: 60 – 20 – 20. The result would be 110 thalers, so says the ordinary economist, and the even more ordinary capitalist says that 10% has been produced in equal proportions by all parts of the capital. Again, 80 thalers of capital would merely be preserved; no change taken place in its value. Only the 20 thalers would have turned into 30; i.e. surplus labour would have increased by 50%, not by 25% as before.

Take the third case: 100: 70 – 20 – 10. Result 110.

Then the invariable value, 90. The new product 20; hence surplus value or surplus time 100%. Here we have three cases in which the profit on the whole capital is always 10, but in the first case the new value created was 25% above the objectified labour spent to buy living labour, in the second case 50%, in the third: 100%.>

The devil take this wrong arithmetic. [5] But never mind. *Commençons de* *nouveau.*

In the first case we had:

Invariable value	*Wage labour*	*Surplus value*	*Total*
60	40	10	110

We continue to presuppose a working day = 12 hours. (We could also assume a growing working day, e.g. *x* hours before, but now *x* + *b* hours, while productive force remains constant; or both factors variable.)

	Hours	*Thalers*	
If the worker produces in	12	50	
then in	1	4 1/6	
then in	9 3/5	40	} in 12 hours 50 thalers
then in	2 2/5	10	

The worker's necessary labour then amounts to 9 3/5 hours (40 thalers); hence surplus labour 2 2/5 hours (value of 10 thalers). 2 2/5 hours is 1/5 of the working day. The worker's surplus labour amounts to 1/5 of the day, i.e. = the value of 10 thalers. Now if we look at these 2 2/5 hours as a percentage which capital has gained above the labour time objectified in 9 3/5 hours, then 2 2/5:9 3/5 = 12/5:48/5, i.e. = 12:48 = 1:4. Thus 1/4 of the capital = 25% of it. Likewise, 10 thalers : 40 thalers = 1:4 = 25%. Now, summarizing the whole result: [6]

No. I	*Original capital:*	*Constant value:*	*Value reproduced for wages:*	*Surplus value from production:*	*Total sum:*	*Surplus time and value:*	*% of objectified labour exchanged:*
	100	60	40	10	110	2 2/5 hours or 10. (2 2/5 of labour)	25%

(It might be said that the *instrument of labour*, its value, has to be not only replaced but reproduced; since it is in fact used up, consumed in production.

This to be looked at under *fixed capital*. In actuality the value of the instrument is transposed to that of the material; to the extent that it is objectified labour, it only changes its form. If in the above example the value of the material was 50 and that of the instrument 10, then now, with the instrument used up by 5, the value of the material is 55 and that of the instrument 5; if it disappears altogether, then that of the material has reached 60. This is an element of the simple production process. Unlike wages, the instrument has not been consumed *outside the production process*.)

Now to the second presupposition:

Original capital:	*Constant Value:*	*Value reproduced for wages:*	*Surplus value from production:*	*Total sum:*
100	80	20	10	110

If the worker produces 30 thalers in 12 hours, then in 1 hour 2 2/4 thalers, in 8 hours 20 thalers, in 4 hours 10 thalers. 10 thalers are 50% of 20 thalers; as are 4 hours out of 8 hours; the surplus value = 4 hours, 1/3 of a day, or 10 thalers surplus value.

Thus:

No. II	*Original capital*	*Constant value:*	*Value reproduced for wages:*	*Surplus value from production:*	*Total sum:*	*Surplus time and value:*	*% on capital:*
	100	80	20 8 hours	10	110	4 hours or 10. 2 working days	50%

In the first case, like the second, the profit on a total capital of 100 = 10%, but in the first case the real surplus value which capital obtains from the production process is 25%, in the second, 50%.

The conditions presupposed in No. II are in themselves as possible as those in No. I. But brought into connection with one another, those of No. II are absurd. Material and instrument have been raised from 60 to 80, the productivity of labour has fallen from 4 1/6 thalers per hour to 2 3/4 and surplus value increased by 100%. (Suppose, however, that the increased expenditure for wages expresses more working days in the first case, fewer in the second, and then the presupposition is correct.) It is in itself irrelevant that necessary wages, i.e. the value of labour expressed in thalers, have fallen. Whether the value of an hour of labour is expressed in 2 thalers or in 4, in both cases the product of 12 hours of labour is exchanged (in circulation) for 12 hours of labour, and in both cases surplus labour appears as surplus value. The absurdity of the presupposition comes from the fact (1) that we have posited 12 hours as the minimum working time; and hence cannot introduce additional or fewer working days; (2) the more we make capital increase on one side, the more we not only make *necessary* labour decline, but have also to decrease its *value*, although the value is the same. In the second case, the price would, rather, have to rise. The fact that the worker can live from less work, i.e. that he produces more in the same number of hours, would have to be shown not in a decrease in the thalers for necessary labour, but in the number of necessary hours. If he gets, as e.g. in the first case, 4 1/6 thalers, but if the use value of this value, which has to be *constant* in order to express *value* (not price), had multiplied, then he no longer needs 9 3/5 but only 4 hours for the reproduction of his living labouring capacity, and this would have to express itself in the surplus over the value. But the way we have set up the presuppositions, our ‘invariable value’ is variable, while the 10% are invariable, here a constant addition to reproductive labour, although it expresses different percentage parts of the same. In the first case the invariable value is smaller than in the second case, but the total product of labour is larger; since, if one part of 100 is smaller, the other has to be larger; and, since absolute labour time is fixed at the identical amount, and since further the total product of labour becomes smaller, in proportion as ‘invariable value’ becomes larger, and larger as the latter becomes smaller, we therefore obtain less product (absolutely) from the same labour time in proportion as more capital is employed. Now, this would be quite correct, since, if out of a given sum such as 100 more is spent as ‘invariable value’, less can be spent for labour time, and thus, *relative* to total capital, less new overall value can be created; but then, if capital is to make a profit, one cannot hold *labour time* constant, as is done here, or, if one holds it constant, the *value of the working hour* cannot become smaller, as it does here; which is impossible if ‘invariable value’ becomes larger and *surplus value* becomes *larger*; the *number of* working hours would have to become smaller. But that is what we have assumed in the example. We assume in the first case that 50 thalers are produced in 12 hours of labour; in the second case, only 30 thalers. In the first, we make the worker work 9 3/5 hours; in the second only 6, although he produces less per hour. It’s absurd. But, understood differently, is there not after all something correct in these figures? Does not absolute new value decrease despite an increase in the relative, as soon as relatively more material and instrument than labour is introduced into the component parts of capital? Relative to a given capital, less living labour is employed; hence, even if the excess of this living labour above its costs is greater, and therefore the percentage of wages rises, i.e. the percentage relative to capital actually consumed, then the absolute new value does not necessarily become relatively smaller than in the case of a capital which employs less material and instrument (and this is the main point of the change in invariable value, i.e. value unchanged as value in the production process) and relatively more living labour; precisely because relatively more living labour is employed? An increase in the productive force then corresponds to the increase in the instrument, since the surplus value of the instrument does not keep pace, as in the previous mode of production, with its use value, its productive force, and since any increase in productive force creates more surplus value, although by no means in the same numerical proportion. The increase in the productive forces, which has to express itself in an enlargement of the value of the instrument – the space it takes up in capital expenditure – necessarily brings with it an increase in the material, since more material has to be worked in order to produce more product. (The increase in the productive force can, however, also relate to quality; but if that is given, only to quantity; or to quantity if quality is given; or to both.) Now, although there is less (necessary) labour in relation to surplus labour, and absolutely less living labour in relation to capital, is it not possible for its surplus value to rise, although in relation to the capital as a whole it declines, i.e. the so-called rate of profit declines? Take for example a capital of 100. Let material be 30 at first. 30 for instrument. (Together, invariable value of 60.) Wages 40 (4 working days). Profit 10%. Here profit is 25% on wages and 10% on capital as a whole. Now let material become 40 and instrument 40. Let productivity double, so that only 2 working days necessary = 20. Now posit that the absolute profit be smaller than 10; i.e. the profit on total capital. Is it not possible for profit on labour employed to be more than 25%, i.e. in the given case, more than merely a fourth of 20? In fact, a third of 20 is 6 2/3; i.e. less than 10, but 33 1/3% of labour employed, while in the previous case it was only 25%. In this case, we would end up with only 106 2/3, while in the previous case we would have had 110, but still, with the same capital (100) the surplus labour, surplus gain relative to labour employed, would be greater than in the first case; but since 50% less labour was employed, in absolute terms, than in the first case, while the profit on labour employed was only 8 1/3 more than in the first case, it follows that the absolute quantity which results has to be smaller, and the same applies to the profit on total capital. For 20 × 33 1/3 is smaller than 40 × 25. This whole instance is improbable and cannot count as a general example in economics; for an increase in the instrument and an increase in the material worked are both presupposed, while not only the relative but the absolute number of workers has declined. (Of course, when two factors = a third, one has to grow smaller as the other grows larger.) But an increase in the value of the instrument in relation to capital as a whole, and an increase in the value of the material, all in all presuppose a division of labour, hence at least an absolute increase in the number of workers, if not an increase relative to capital as a whole. However, take the case of the lithographing machine, which everyone can use to make lithographs without special skill; suppose the value of the instrument immediately upon its invention to be greater than that which 4 workers absorbed before these handy things were invented; it now requires only 2 workers (here, as with many instrument-like machines, no further division of labour takes place; instead, the qualitative division disappears); let the instruments originally have a value of only 40, but let 4 working days be necessary (necessary, here, for the capitalist to make a profit). (There are machines, e.g. forced air heating ducts, where labour as such disappears altogether except at a single point; the duct is open at one point, and carries heat to the others; no workers are required at all. This the case generally (see Babbage) [7] with energy transmission, where, previously, energy had to be carried in material form by numbers of workers, here firemen, from one point to another – where the transmission from one room to another, which has now become a physical process, appeared as the labour of numbers of workers.) Now, if he uses this lithographing machine as a source of income, as capital, and not as use value, then the material must necessarily increase, since he can put out more lithographs in the same amount of time, which is precisely where this greater profit comes from. Let this lithographer then employ an instrument to the amount of 40, material 40, 2 working days (20) which [give] him 33 1/3%, i.e. 6 2/3 out of an objectified labour time of 20; then his capital, like the other's, consists of 100, only yields 6 2/3%, but he gains 33 1/3 on labour employed, while the other gains 10 on capital, but only 25% on labour. The value obtained from labour employed may be smaller, but the profits on the whole capital are greater if the other elements of capital are relatively smaller. Despite this, the business at 6 2/3% on the total capital and 33 1/3% on labour could become more profitable than the earlier one based on 25% on labour and 10% profit on the total capital. Suppose e.g. that grain prices etc. rose so that the maintenance of the worker rose by 25% in value. The 4 working days would now cost the first lithographer 50 instead of 40. His instruments and material would remain the same: 60 thalers. He would then have to lay out a capital of 110. With this capital, his profit on the 50 thalers for 4 working days would be 12 (25%). Hence 12 thalers on 110 (i.e. 9 1/6% on the total capital of 110). The other lithographer: machine 40, material 40; but the 2 working days will cost him 25% more than 20, i.e. 25. He would thus have to lay out 105; his surplus value on labour 33 1/3%, i.e. 1/3, is 8 1/3. He would gain then, 8 1/3 on 105; 13 1/8%. Then suppose a 10 year cycle with 5 bad and 5 good harvests at the above average proportions; then the first lithographer would gain 50 thalers of interest on the second during the first 5 years; in the last 5 45 5/6; altogether 95 5/6 thalers; average interest over the 10 years 9 7/12 thalers. The other capitalist would have gained 31 1/3 in the first 5 years, 65 5/8 in the last; 96 23/24 altogether; a 10-year average of 9 84/120. Since No. II uses up more material at the same price, he sells cheaper. It could be said in reply that he sells dearer because he uses up more instrument; especially because he uses up more of the value of the machine in proportion as he uses up more material; however, it is in practice not true that machines wear out and have to be replaced more rapidly as they work more material. But all this is beside the point. Let the relation between the value of the machine and that of the material be constant in both cases.

This example attains significance only if we assume a smaller capital which employs more labour and less material and machinery, but yields a higher percentage on the total capital; and a larger capital employing more machinery and more material, as many working days in absolute numbers but relatively fewer, and a smaller percentage on the whole, because less on labour, being more productive, division of labour used, etc. It also has to be postulated (which was not done above) that the use value of the machine significantly greater than its value; i.e. that its devaluation in the service of production is not proportional to its increasing effect on production.

Thus, as above, a press (first, hand-operated printing press; second, self-acting printing press).

Capital I, 100, uses 30 in material; 30 for the manual press; 4 working days = 40 thalers; gain 10%; hence 25% on living labour (1/4 surplus time).

Capital II, 200, uses 100 in materials; 60 in press, 4 working days (40 thalers); gain on the 4 working days 13 1/3 thalers = 1 working day and 1/3, compared to only 1 working day in the first case; total sum: 213 1/3. I.e. 6 2/3%, compared to 10% in the first case. Nevertheless, the surplus value on the labour which has been employed is 13 1/3 in this second case, as against 10 in the first; in the first, 4 days create 1 surplus day in 4 working days; in the second, 4 days create 1 1/3 surplus days. But the rate of profit on the total capital is 1/3 or 33 1/3% smaller than in the first; the total amount of the gain is 1/3 greater. Now let us suppose that the 30 and the 100 in material are sheets of book paper, and that the instruments wear out in the same space of time, say 10 years or 1/10 per year. Then No. I has to replace 1/10 of 30 in material, i.e. 3; No. II, 1/10 of 60, i.e. 6. The material does not enter further into annual production (which may be regarded as 4 working days of 3 months each) on either side, see above.

Capital I sells 30 sheets at 30 for materials + 3 for instrument + 50 (objectified labour time) (production time) = 83.

Capital II sells 100 sheets at 100, material, + 6, instrument, + 53 1/3 = 159 1/3.

Capital I sells 30 sheets for 83 thalers, 1 sheet at 83/80 thalers = 2 thalers, 23 silver groschen.

Capital II sells 100 sheets for 159 thalers, 10 silver groschen; 1 sheet at

$\frac{\text{159 thalers 10 silver groschen}}{100}$ i.e., 1 thaler, 17 silver groschen, 8 pfennigs.

It is clear then that Capital I is done for, because its selling price is infinitely too high. Now, although in the first case the profit on total capital was 10% and in the second case only 6 2/3%, the first capital only took in 25% on labour time, while the second takes 33 1/3%. With Capital I, necessary labour is greater relative to the total capital; and hence surplus labour, while smaller in absolute terms than with Capital II, shows up as a higher rate of profit on the smaller total capital. 4 working days at 60 are greater than 4 at 160; in the first, 1 working day corresponds to a capital of 15; in the second, 1 working day corresponds to 40. But with the second capital, labour is more productive (which is given both in the *greater* amount of machinery, hence the greater amount of space that it takes up among the value components of capital; and in the greater amount of material in which a working day, which consists of a greater proportion of surplus time and hence uses more material in the same time, is expressed). It creates more surplus time (relative surplus time, i.e. determined by the development of the force of production). In the first case, surplus time is 1/4, in the second, 1/3. It therefore creates more use values and a higher exchange value in the same amount of time; but the latter not in proportion with the former, since, as we saw, exchange value does not rise in the same numerical proportion as the productivity of labour. The fractional price is therefore smaller than the total production price – i.e. the fractional price multiplied by the amount of fractional prices produced is greater. Now, if we had assumed an *absolutely greater* number of working days than in No. I, although a relatively smaller number, then the matter would have been even more striking. The profit of the larger capital, working with more machinery, therefore appears smaller than that of the smaller capital working with relatively or absolutely more living labour, precisely because the *higher profit on living labour* appears as smaller, when calculated on the basis of a total capital in which living labour makes up a lesser proportion of the whole, than the *lower profit on living labour* which makes up a larger proportion of the smaller total capital. But the fact that No. II can employ more material, and that a larger proportion of the total value is in the instrument, is only the expression of the productivity of labour.

This, then, is the unfortunate Bastiat's famous riddle; he had firmly convinced himself – to which Mr Proudhon had no answer – that because the rate of profit of the larger and more productive total capital is smaller, it follows that the worker's share has grown larger, whereas precisely the *opposite* is the case; his surplus labour has grown larger. [8]

Nor does Ricardo seem to have understood the matter, for otherwise he would not have tried to explain the periodic decline of profit merely by the rise in wages caused by the rise in grain prices (and hence of rent). [9] But at bottom, surplus value – in so far as it is indeed the foundation of profit, but still distinct from profit commonly so-called – has never been developed. The unfortunate Bastiat would have said in the above case that in the first example the profit was 10% (i.e. 1/10), in the second only 6 1/4%, i.e. 1/16 (leaving out the percentage), so that the worker receives 9/10 in the first case, 15/16 in the second. The relation is correct in neither of the two cases, nor is their relation to one another correct. Now, as far as the further relation of the new value of capital to capital as *indifferent total value* is concerned (and this is how capital as such appeared to us at the beginning, before we moved on into the production process, and it must again appear to us in this way at the end of the process), this is to be developed partly under the rubric of *profit*, where the new value obtains a new character, and partly under the heading of *accumulation*. We are here initially concerned only with developing the nature of surplus value as the equivalent of the absolute or relative labour time mobilized by capital above and beyond necessary labour time.

The consumption, in the production process, of the element of value consisting of the instrument cannot in the least [serve to] distinguish the instrument of labour from the material – here, where all that is to be explained is the creation of surplus value, self realization. This is because this consumption is part of the simple production process itself, hence the value of the consumed instrument (whether it be the *simple use value* of the instrument itself or the exchange value, if production has already progressed to where there is a division of labour and where at least the surplus is exchanged) has to be recovered again in the value (exchange value) or the use value of the product – so that the process can begin anew. The instrument loses its use value in the same proportion as it helps to raise the exchange value of the raw material and serves as a means of labour. This point must, indeed, be examined, because the distinction between the invariable value, the part of capital which is preserved; that which is reproduced (*reproduced* for capital; from the standpoint of the real production of labour – *produced*); and that which is newly produced, is of essential importance.

Multiplication of simultaneous working days. **(Accumulation of capital.) –** ***Growth of the constant part of capital in relation to the variable part spent on wages = growth of the productivity of labour. – Proportion in which capital has to increase in order to employ the same number of workers if productivity rises***

It is now time to finish with the question of the value resulting from the growth of the productive forces. We have seen: this creates a *surplus value* (not merely a greater use value) just as in the case of an absolute increase in surplus labour. If a certain limit is given, say e.g. that the worker needs only half a day in order to produce his subsistence for a *whole* day – and if the natural limit has been reached – then an increase of absolute labour time is possible only if more workers are employed *at the same time*, so that the real working day is simultaneously multiplied instead of only lengthened (in the given conditions, the individual worker can work no more than 12 hours; if a surplus time of 24 hours is to be gained, then there have to be 2 workers). Capital in this case, before entering the self-realization process, has to buy 6 additional hours of labour in the act of exchange with the worker, i.e. has to lay out a greater part of itself; at the same time it has to lay out more for material, on the average (beside the fact that the extra worker has to be *available*, i.e. that the working population has to have grown). Hence the possibility of this further realization process depends here on a previous accumulation of capital (as regards its material existence). If, however, productivity increases, and hence relative surplus time – at the present point we can still regard capital as always directly engaged in the production of subsistence, raw materials etc. – then less expenditure is necessary for wages and the growth in the material is created by the realization process itself. But this question belongs, rather, with the *accumulation* of capitals.

We now come to the point where we last broke off. [10] An increase in productivity increases the *surplus value*, although it does not increase the absolute amount of exchange values. It increases values because it creates a new *value as value*, i.e. a value which is not merely an equivalent destined for exchange, but which asserts itself as such; in a word, more money. The question is: does it ultimately also increase the amount of exchange values? This is, at bottom, admitted; for even Ricardo admits that along with the accumulation of capitals there is an increase in savings, hence a growth in the exchange values produced. The growth of savings means nothing more than the growth of independent values – of money. But Ricardo's demonstration contradicts his own assertion.

Our old example. 100 thalers capital; 60 thalers in constant value; 40 in wages; produces 80; hence product = 140. * Let these 40 in surplus value be absolute labour time.

> * Here we see again that the surplus value on the whole of the capital = to half of the newly produced value, since a half of the latter = to necessary labour. The relation between this surplus value, which is always equal to surplus time, i.e. = to the worker's total product minus the part which forms his wage, depends (1) on the relation between the constant part of capital and the productive part; (2) between necessary labour time and surplus time. In the above case, the relation of surplus time to necessary time is 100%; gives 40% on a capital of 100; hence (3) it depends further, not only on the relation given above in (2), but also on the absolute magnitude of necessary labour. If, in a capital of 100, the constant part were 80, then the part exchanged for necessary labour would be = 20, and if this created 100% surplus time, the profit on capital would be 20%. But if the capital were 200 with the same relation between the constant and the variable part (i.e. 3/5 to 2/5), then the total would be 280, which is 40 out of 100. In this case the absolute amount of profit would rise from 40 to 80, but the relation would remain at 40%. However, if out of the 200 the constant element were 120 and the quantity of necessary labour 80, but the latter increased by only 10%, i.e. 8, then the total sum would be = 208, i.e. a profit of 4%; if it increased by only 5, then the total 205, i.e. 2 1/2%.

Now suppose that productivity doubles: then, if a wage of 40 gives 8 hours of necessary labour, the worker could now produce a whole day of living labour in 4 hours. Surplus time would then increase by 1/3 (2/3 of a day to produce a whole day before, now 1/3). 2/3 of the product of the working day would be surplus value, and if the hour of necessary labour = 5 thalers (5 × 8 = 40), then he would now need only 5 × 4 = 20 thalers. For capital, then, a surplus gain of 20, i.e. 60 instead of 40. At the end, 140, of which 60 = the constant value, 20 = the wage and 60 = the surplus gain; together, 140. The capitalist can then begin production anew with 80 thalers of capital:

Let capitalist A on the same stage of old production invest his capital of 140 in new production. Following the original proportions, he needs 3/5 for the invariable part of capital, i.e. 3 × 140/5 = 3 × 28 = 84, leaving 56 for necessary labour. Before, he spent 40 on labour, now 56; 2/5 of 40 additionally. Then at the end, his capital = 84 + 56 + 56 = 196.

Capitalist B on the higher stage of production would similarly employ his 140 thalers for new production. If out of a capital of 80 he needs 60 for invariable value and only 20 for labour, then out of a capital of 60 he needs 45 for invariable value and 15 for labour; thus the total would be = 60 + 20 +20 = 100 in the first and, secondly, 45 + 15 + 15 = 75. Thus his total yield is 175, while that of the first = 196. An increase in the productivity of labour means nothing more than that the same capital creates the same value with less labour, or that less labour creates the same product with more capital. That less necessary labour produces more surplus labour. The necessary labour is smaller in relation to capital; for the process of its realization this is obviously the same as: capital is larger in relation to the necessary labour which it sets into motion; for the same capital sets more surplus labour in motion, hence less necessary labour. [*]

---

[*] If it is postulated, as in our case, that the capital remains the same, i.e. that both begin again with 140 thalers, then in the case of the more productive capital, a larger part has to go to capital (i.e. to its invariable part), while with the less productive capital, a larger part to labour. The first capital of 140 thus sets into motion a necessary labour of 56, and this necessary labour presupposes an invariable part of 84 out of the total capital. The second sets labour in the amount of 20 + 15 = 35 into motion, and an invariable capital of 60 + 45 = 105 (it further follows from what was developed earlier that an increase in the force of production does not proportionately

> increase value). In the first case, as already shown above, the absolute new value is greater than in the second, because the mass of labour employed is greater in relation to the invariable part; while in the second the former is smaller, precisely because labour is more productive. However (1) the difference between the new value of 60 in one case and 40 in the other means that the first cannot begin production anew with the same capital as the second; for a part of the new value on both sides has to enter into circulation as an equivalent so that the capitalist can live, and live from his capital. If both of them eat up 20 thalers then the first begins anew with a capital of 120, the other also with 120 etc. See above. Return to this whole matter again; [11] but the question of the relation between the new value created by the increased force of production and the new value created by absolute increases in labour belongs in the chapter on *accumulation and profit*.

It is sometimes said about machinery, therefore, that it *saves labour*; however, as Lauderdale correctly remarked, the mere saving of labour is not the characteristic thing; [12] for, with the help of machinery, human labour performs actions and creates things which without it would be absolutely impossible of accomplishment. The latter concerns the use value of machinery. What is characteristic is the *saving* of necessary labour and the creating of *surplus labour.* The higher productivity of labour is expressed in the fact that capital has to buy a smaller amount of necessary labour in order to create the same value and a greater quantity of use values, or that less necessary labour creates the same exchange value, realizes more material and a greater mass of use values. Thus, *if the total value of the capital remains the same*, an increase in the productive force means that the constant part of capital (consisting of machinery and material) grows relative to the variable, i.e. to the part of capital which is exchanged for living labour and forms the wage fund. This means at the same time that a smaller quantity of labour sets a larger quantity of capital in motion. If the *total value of capital* entering into the production process increases, then the wage fund (this variable part of capital) must decrease *relatively*, compared to the relation if the productivity of labour, i.e. the relation of necessary to surplus labour, had remained the same. Now let us assume in the above case that the capital of 100 is agricultural capital. Then, 40 thalers for seeds, fertilizer etc.; 20 thalers instrument of labour, and 40 thalers wage labour, at the old level of production. (Let these 40 thalers = 4 days of necessary labour.) At the old production level, these create a total of

140. Now let fertility double, owing to improvement either in the instrument or in the fertilizer etc. In this case the product has to = 140 thalers (given that the instrument is entirely consumed). Let fertility double, so that the price of the necessary working day falls by half; so that only 4 necessary half days of work (i.e. 2 whole ones) are necessary in order to produce 8. 2 working days to produce 8 is the same as when 1/4 of each working day (3 hours) is required for necessary labour. Now, instead of 40 thalers, the farmer has to spend only 20 for labour. Thus at the end of the process the component parts of capital have changed; from the original 40 for seed etc., which now have double the use value; 20 for instrument and 20 for labour (2 whole working days). Before the relation of the constant part of capital to the variable = 60:40 = 3:2; now 80:20 = 4:1. Looking at the whole capital, necessary labour was = 2/5; now 1/5. Now, if the farmer wants to continue to use labour in the old relation, then by how much would his capital have to increase? Or – in order to avoid the *nefarious presupposition* that he continued to operate with a constant capital of 60 and a wage fund of 40 – after a doubling of productive force, which introduces false relations; * because it presupposes that, despite the doubled force of production, capital continued to operate with the same component parts, to employ the same quantity of necessary labour without spending more for raw material and instrument of labour; † then, therefore, productivity doubles, so that he now needs to spend only 20 thalers on labour, whereas he needed 40 before. (If it is given that 4 whole working days were necessary, each = 10 thalers, in order to create a surplus of 4 whole working days, and if this surplus is provided for him by the transformation of 40 thalers of cotton into yarn, then he now needs only 2 whole working days in order to create the same value, i.e. that of 8 working days; the value of the yarn expressed a surplus time of 4 working days before, now of 6. Or, each of the workers needed 6 hours of necessary labour time before in order to create 12; now 3. Necessary labour time was 12 × 4 = 48, or 4 days. In each of these days, the surplus time was = 1/2 day (6 hours). It now amounts to only 12 × 2 = 24 or 2 days; 3 hours per day. In order to bring forth the surplus value, each of the 4 workers would have to work 6 × 2 hours; i.e. 1 day; now he needs to work only 3 × 2 hours; i.e. 1/2 day. Now, whether 4 work 1/2 a day or 2 a whole (1) day is the same. The capitalist could dismiss 2 workers. He would even have to dismiss them, since a

certain quantity of cotton is only enough to make a certain quantity of yarn; thus he cannot order 4 whole days of work any more, but only 4 half days. But if the worker has to work 12 hours in order to obtain 3 hours, i.e. his *necessary* wage, then, if he works 6 hours, he will obtain only 1 1/2 hours of exchange value. But if he can live for 12 hours with 3 hours of necessary labour, then with it he can live only 6 hours. Thus if all 4 workers were to be employed, each of the 4 could live only half a day; i.e. the same capital cannot keep all 4 alive as *workers*, but only 2. The capitalist could pay 4 out of the old fund for 4 half days of work; then he would pay 2 too many and would make the workers a present of the productive force; since he can use only 4 half days of living labour; such 'possibilities' neither occur in practice, nor can we deal with them here, where we are concerned with the relation of capital as such.) Now 20 thalers of the capital of 100 are not directly employed in production. The capitalist uses 40 thalers of raw material, 20 for instrument, together 60 as before, but now only 20 thalers for labour (2 working days). Of the whole capital of 80 he uses 3/4 (60) for the constant part and only 1/4 for labour. Then if he employs the remaining 20 in the same way, 3/4 for constant capital, 1/4 for labour; then 15 for the first, 5 for the second. Now since 1 working day = 10 thalers (given), 5 would be only = 6 hours = 1/2 working day. With the new value of 20, gained through productivity, capital could buy only 1/2 a working day more, if it continues to realize itself in the same proportion. It would have to grow threefold (namely, 60) (together with the 20 = 80) in order to employ the 2 dismissed workers for the previous 2 full working days. In the new relation, the capital uses 3/4 in constant capital in order to employ 1/4 as wage fund.

[*] Although in the case e.g. of the farmer this is quite correct, if the seasons bring a doubling of fertility, and correct for every industrialist if the force of production doubles not in his branch, but in the branch whose output he uses; i.e. if e.g. raw cotton cost 50% less and grain (i.e. wages) and the instrument likewise; he would then continue as before to spend 40 thalers for raw cotton, but in twice the quantity, 20 for machinery, 40 for labour.

[†] Suppose cotton alone doubled in productivity, the machine remains the same, then – this to be examined further.

Thus if 20 is the whole capital, 3/4 i.e. 15 constant and 1/4 labour (i.e. 5) = 1/2 a working day.

With a whole capital of 4 × 20, hence 4 × 15 = 60 constant, hence 4 × 5 = 20 wages = 4/2 working days = 2 working days.

Therefore, if the productive force of labour doubles, so that a capital of 60 thalers in raw materials and instrument now needs only 20 thalers in labour (2 working days) for its realization, whereas it needed 100 before, then the total capital of 100 would have to grow to 160, or the capital of 80 now being dealt with would have to double in order to retain all the labour put out of work. But the doubling of productive force creates a new capital of only 20 thalers = 1/2 of the labour time employed earlier; and this is only enough to employ 1/2 a working day additionally. Before the doubling of the productive force, the capital was 100 and employed 4 working days (on the supposition that 2/5 = wage fund of 40); now, when the wage fund has fallen to 1/5 of 100, to 20 = 2 working days (but to 1/4 of 80, the capital newly entering into the realization process), it would have to rise to 160, by 60%, in order still to be able to employ 4 working days as before. It can only employ 1/2 a new working day with the 20 thalers drawn from the increase in the productive force, if the whole old capital continues operating. Before, it employed with 100, 16/4 (4 days) working days; it could now employ only 5/4. Therefore, when the force of production doubles, capital does not need to double in order to set the same necessary labour into motion, 4 working days; i.e. it does not need to rise to 200, but needs to rise only by double the whole, minus the part deducted from the wage fund. (100 − 20 = 80) × 2 = 160. (By contrast, the first capital, before the increase in productive force, which divided 100 as 60 constant 40 wages (4 working days), in order to employ two additional days, would need to grow from 100 to only 150; i.e. 3/5 constant capital (30) and 2/5 wage fund (20). If it is given that the working day doubles in both cases, then the second would amount to 250 at the end, the first only 160.) Of the part of capital which is withdrawn from the wage fund owing to the increase in the force of production, one part has to be transformed again into raw material and instrument, another part is exchanged for living labour; this can take place only in the proportions between the different parts which are posited by the new productivity. It can no longer take place in the old proportion, for the relation of the wage fund to the constant fund has decreased. If the capital of 100 first used 2/5 for wage fund (40) and, owing to a doubling of productive force, then used only 1/5 (20), then 1/5 of the capital has become free (20 thalers); and the employed part, 80, uses only 1/4 as wage fund. Thus, of the 20, similarly, only 5 thalers (1/2 working day). The whole capital of 100 therefore now employs 2 1/2 working days; or, it would have to grow to 160 in order to employ 4 again.

If the original capital had been 1,000, divided in the same way: 3/5 constant capital, 2/5 wage fund, then 600 + 400 (let 400 equal 40 working days; each working day = 10 thalers). Now double the productive force of labour, i.e. only 20 working days required for the same product (= 200 thalers), then the capital necessary to begin production anew would be = 800; that is 600 + 200; 200 thalers would have been set free. Employed in the same relation, then 3/4 for constant capital = 150 and 1/4 wages = 50. Thus, if the 1,000 thalers are employed in their entirety, then now 750 constant + 250 wage fund = 1,000 thalers. But 250 wage fund would be = 25 working days (i.e. the new fund can employ labour time only in the new relation, i.e. at 1/4; in order to employ the entire labour time as before, it would have to *quadruple*). The liberated capital of 200 would employ a wage fund of 50 = 5 working days (1/4 of the liberated labour time). (The part of the labour fund disconnected from capital is itself employed as capital at only 1/4 for labour fund; i.e. precisely in the relation in which that part of the new capital which is labour fund stands to the total sum of the capital.) Thus in order to employ 20 working days (4 × 5 working days), this fund would have to grow from 50 to 4 × 50 = 200; i.e. the liberated part would have to grow from 200 to 600, i.e. triple; so that the entire new capital would amount to 800. Then the total capital, 1,600; of this, 1,200 constant part and 400 labour fund. Thus if a capital of 1,000 originally contained a labour fund of 400 (40 working days), and if, owing to a doubling of productive force, it now needs to employ a labour fund of only 200 in order to buy *necessary* labour, i.e. only 1/2 of the previous labour; then the capital would have to grow by 600 in order to employ all the previous labour in its entirety (in order to gain the same amount of surplus time). It would have to be able to employ twice the labour fund, i.e. 2 × 200 = 400; but, since the relation of the labour fund to the total capital is now = 1/4, this requires a total capital of 4 × 400 = 1,600. *

[*] The total capital which would be necessary in order to employ the old labour time is therefore = *to the old labour fund multiplied by the denominator* of the fraction which now expresses the relation of the labour fund to the new total capital. If the doubling of productive force has reduced the latter to 1/4, then multiplied by 4; if to 1/3, then multiplied by 3. If the productive force has doubled, then necessary labour, and thereby the labour fund, is reduced to 1/2 of its earlier value; but this makes up 1/4 relative to the new total capital of 800 or 1/5 relative to the old total capital of 1,000. *Or the new total capital is* = 2 × *the old capital minus the liberated part of the labour fund*; (1,000 − 200) × 2 = 800 × 2 = 1,600. The new total capital expresses the total sum of constant and variable capital required in order to employ half of the old labour time (1/3, 1/4, 1/*x*, etc, depending on whether the force of production increased 3 ×, 4 ×, *x* ×); 2 × then the capital required to employ all of it (or 3 ×, 4 ×, etc., depending on the relation in which the productive force has grown). The original relation of the parts of capital must here always be given (*technologically*); on this depends, e.g., in what ratios the multiplication of productive force expresses itself as a division of *necessary labour.*

Or, which is the same thing, it is = 2 × *the new capital* which owing to the new productive force replaces the old in production (800 × 2) (thus if the productive force had quadrupled, quintupled etc. = 4 ×, 5 × *the new capital* etc. If the force of production has doubled, then *necessary labour* is reduced to 1/2; likewise the labour fund. Thus if it amounted, as in the above case of the old capital of 1,000, to 400, i.e. 2/5 of the total capital, then, afterwards, 1/5 or 200. This relation, by which it is reduced, is the liberated part of the labour fund = 1/5 of the old capital = 200. 1/5 of the old = 1/4 of the new. The new capital is = to the old + 3/5 of the same. These trivia more closely later etc.)

Given the same original relations between the parts of the capital and the same increase in the productive force, the largeness or smallness of the capital is completely irrelevant for the general theses. Quite another question is whether, when capital grows *larger*, the relations remain the same (but this belongs under accumulation). But, given this, we see how an increase in the force of production changes the relations between the component parts of capital. If in both cases 3/5 was originally constant and 2/5 labour fund, then doubling the productive force acts in the same way on a capital of 100 as on one of 1,000. (The word *labour fund* is here used only for convenience's sake; we have not yet developed capital in this *specificity* [*Bestimmtheit*]. So far two parts; the one exchanged for commodities (material and instrument), the other for labour capacity.) (The *new capital*, i.e. the part of the old capital which represents its *function*, is = the old minus the liberated part of the labour fund; this liberated part, however, = the fraction which used to express necessary labour (or, same thing, the labour fund) divided by the multiplier of the productive force. Thus, if the old capital = 1,000 and the fraction expressing necessary labour or the labour fund = 2/5, and if the force of production doubles, then the new capital which represents the function of the old = 800, i.e. 2/5 of the old capital = 400; this divided by 2, the multiplier of productive force, = 2/10 = 1/5 = 200. Then the new capital = 800 and the liberated part of the labour fund = 200.)

We have seen that under these conditions a capital of 100 thalers has to grow to 160, and a capital of 1,000 to 1,600, in order to retain the same labour time (of 4 or 40 working days) etc.; both have to grow by 60%, i.e. 3/5 of themselves (of the old capital), in order to be able to re-employ the liberated labour time (in the first case 20 thalers, in the second 200) of 1/5 – the liberated labour fund – as such.

Percentage of total capital can express very different relations. – Capital (like property) rests on **productivity of labour**

<*Notabene*. We saw above that identical percentages of the total capital can express very different relations in which capital creates its surplus value, i.e. posits surplus labour, relative or absolute. [13] If the relation between the invariable value-part of capital and the variable part (that exchanged for labour) such that the latter = 1/2 the total capital (i.e. capital 100 = 50 (constant) + 50 (variable), then the part exchanged for labour would have to increase by only 50% in order to yield 25% on the capital; i.e. 50 + 50 (+ 25) = 125; while in the above example 75 + 25 (+ 25) = 125; i.e. the part exchanged for living labour increases by 100% in order to yield 25% on the capital. Here we see that, if the relations remain the same, the same percentage on the total capital holds no matter how big or small it may be; i.e. if the relation of the labour fund to the total capital remains the same; thus, above, 1/4. Thus: 100 yields 125, 80 yields 100, 1,000 yields 1,250, 800 yields 1,000, 1,600 yields 2,000 etc., always =

25%. If capitals whose component parts are in different relations, including therefore their forces of production, nevertheless yield the same percentages on total capital, then the real surplus value has to be very different in the different branches.>

<Thus the example is correct, the productive force compared under the same conditions with the same capital *before* the rise in productive force. Let a capital of 100 employ constant value 50, labour fund = 50. Let the fund increase by 50%, i.e. 1/2; then the total product = 125. Let the labour fund of 50 thalers employ 10 working days, pay 5 thalers per day. Since the new value is 1/2, the surplus time has to be = 5 working days; i.e. the worker who needed to work only 10 working days in order to live for 15 has to work 15 for the capitalist in order to live for 15; and his surplus labour of 5 days constitutes capital's surplus value. Expressed in hours, if the work day = 12 hours, then surplus labour = 6 per day. Thus in 10 days or 120 hours, the worker works 60 hours = 5 days too many. But now with the doubling of productivity, relations within the 100 thalers would be 75 and 25, i.e. the same capital now needs to employ only 5 workers in order to create the same value of 125; the 5 working days then = 10; doubled; i.e. 5 working days are paid, 10 produced. The worker would need to work only 5 days in order to live 10 (before the increase in productive force he had to work 10 to live 15; thus, if he worked 5, he could live only 7 1/2); but he has to work 10 for the capitalist in order to live 10; the latter thus makes a profit of 5 days; 1 day per day; or, expressed in days, the worker had to work 1/2 to live 1 before (i.e. 6 hours to live 12); now he needs to work only 1/4 to live 1 (i.e. 3 hours). If he worked a whole day, he could live 2; if he worked 12 hours, 24; if he worked 6, 12 hours. But he now has to work 12 hours to live 12. He would need to work only 1/2 in order to live 1; but he has to work 2 × 1/2 = 1 to live 1. In the old state of the productive force, he had to work 10 days to live 15; or 12 hours to live 18; or 1 hour to live 1 1/2, or 8 hours to live 12, i.e. 2/3 of a day to live 3/3. But he has to work 3/3 to live 2/3, i.e. 1/3 too much. The doubling of the productive force increases the relation of surplus time from 1:1 1/2 (i.e. 50%) to 1:2 (i.e. 100%). In the earlier labour time relation: he needed 8 to live 12, i.e. 2/ 3 of the whole day was necessary labour; he now needs only 1/2, i.e. 6, to live 12. That is why capital now employs 5 workers instead of 10. If the 10 (cost 50) produced 75 before, then now the 25,

50: i.e. the former only 50%, the second 100. The workers work 12 hours as before; but in the first case capital bought 10 working days, now merely 5; because the force of production doubled, the 5 produce 5 days of surplus labour; because in the first case 10 working days yielded only 5 days of surplus labour; now, with the force of production doubled, i.e. risen from 50% to 100% – 5, 5; in the first case 120 working hours (= 10 working days) produce 180; in the second, 60, 60; i.e. in the first case, the surplus time is 1/3 of the whole day (50% of necessary labour) (i.e. 4 hours out of 12; necessary time 8); in the second case surplus time is 1/2 the whole day (100% of necessary labour) (i.e. 6 hours out of 12; necessary time 6); hence the 10 days yielded 5 days of surplus time (surplus labour) in the first case, and in the second the 5 yield 5. Thus relative surplus time has doubled; relative to the first relation it grew by only 1/2 compared to 1/3; i.e. by 16 4/6%.>

	constant		*variable*	
100	60	+	40	(original relation)
100	75	+	25	(+ 25) = 125 (25%)
160	120	+	40	(+ 40) = 200 (25%)

Since surplus labour, or surplus time, is the presupposition of capital, it therefore also rests on the fundamental presupposition that there exists a surplus above the labour time necessary for the maintenance and reproduction of the individual; that the individual e.g. needs to work only 6 hours in order to live one day, or 1 day in order to live 2 etc. With the development of the forces of production, necessary labour time decreases and surplus labour time thereby increases. Or, as well, that one individual can work for 2 etc. (‘*Wealth is disposable* time and nothing more. ... If the whole labour of a country were sufficient only to raise the support of the whole population, there would be no *surplus labour*, consequently nothing that can be allowed to accumulate as capital . . . Truly wealthy a nation, if there is *no interest* or if the working day is 6 hours rather than 12 ... Whatever may be *due* to the capitalist, he can only receive the *surplus labour* of the labourer; for the labourer must live.’ (*The Source and Remedy of the National Difficulties*.) [14]

‘*Property*. Origin in the productivity of labour. If one can produce only enough for one, everyone worker; there can be no property. When one man’s labour can maintain five, there will be four idle men for one employed in production. Property grows from the improvement in the mode of production … The growth of the property, this greater ability to maintain idle men and unproductive industry = capital … machinery itself can seldom be applied with success to abridge the labours of an individual: *more time would be lost in its construction than could be saved by its application. It is only really useful when it acts on great masses, when a single machine can assist the labours of thousands.* It is accordingly in the most populous countries where there are most idle men that it is always most abundant. It is not called into action by scarcity of men, but by the facility with which they are brought together … Not 1/4 of the English population provides everything that is consumed by all. Under William the Conqueror for example the amount of those directly participating in production much greater relative to the idle men.’ (Ravenstone, IX, 32.) [15]

Just as capital on one side creates surplus labour, surplus labour is at the same time equally the presupposition of the existence of capital. The whole development of wealth rests on the creation of disposable time. The relation of *necessary* labour time to the *superfluous* (such it is, initially, from the standpoint of necessary labour) changes with the different stages in the development of the productive forces. In the less productive [16] stages of exchange, people exchange nothing more than their *superfluous labour time*; this is the measure of their exchange, which therefore extends only to superfluous products. In production resting on capital, the existence of *necessary* labour time is conditional on the creation of *superfluous* labour time. In the lowest stages of production, firstly, few human needs have yet been produced, and thus few to be satisfied. Necessary labour is therefore restricted, not because labour is productive, but because it is not very necessary; and secondly, in all stages of production there is a certain common quality [*Gemeinsamkeit*] of labour, *social* character of the same, etc. The force of social production develops later etc. (Return to this.) [17]

Increase of surplus labour time. Increase of simultaneous working days* (Population). *(Population can increase in proportion

as **necessary labour time** *becomes smaller, i.e. the time required to produce living labour capacities decreases.) – Surplus capital and surplus population. – Creation of free time for society*

Surplus time is the excess of the working day above that part of it which we call *necessary* labour time; it exists secondly as the multiplication of *simultaneous working days*, i.e. of the *labouring population.* (It can also be created – but this is mentioned here only in passing, belongs in the chapter on wage labour – by means of forcible prolongation of the working day beyond its natural limits; by the addition of women and children to the labouring population.) The first relation, that of the surplus time and the necessary time in the day, can be and is modified by the development of the productive forces, so that necessary labour is restricted to a constantly smaller fractional part. The same thing then holds relatively for the population. A labouring population of, say, 6 million can be regarded as one working day of 6 × 12, i.e. 72 million hours: so that the same laws applicable here.

It is a law of capital, as we saw, to create surplus labour, disposable time; it can do this only by setting *necessary labour* in motion – i.e. entering into exchange with the worker. It is its tendency, therefore, to create as much labour as possible; just as it is equally its tendency to reduce necessary labour to a minimum. It is therefore equally a tendency of capital to increase the labouring population, as well as constantly to posit a part of it as surplus population – population which is useless until such time as capital can utilize it. (Hence the correctness of the theory of surplus population and surplus capital.) It is equally a tendency of capital to make human labour (relatively) superfluous, so as to drive it, as human labour, towards infinity. Value is nothing but objectified labour, and surplus value (realization of capital) is only the excess above that part of objectified labour which is necessary for the reproduction of labouring capacity. But labour as such is and remains the presupposition, and surplus labour exists only in relation with the necessary, hence only in so far as the latter exists. Capital must therefore constantly posit necessary labour in order to posit surplus labour; it has to multiply it (namely the *simultaneous* working days) in order to multiply the surplus; but at the same time it must suspend them as necessary, in order to posit them as surplus labour. As regards the single working day, the process is of course simple: (1) to lengthen it up to the limits of natural possibility; (2) to shorten the necessary part of it more and more (i.e. to increase the productive forces without limit). But the working day, regarded spatially – time itself regarded as space – is *many working days alongside one another*. The more working days capital can enter into exchange with at once, during which it exchanges *objectified for living labour*, the greater its realization *at once*. It can leap over the *natural* limit formed by one individual's living, working day, *at a given stage in the development of the forces of production* (and it does not in itself change anything that this stage is changing) only by positing *another* working day alongside the *first* at the same time – by the spatial addition *of more simultaneous working days*. E.g. I can drive the surplus labour of A no higher than 3 hours; but if I add the days of B, C, D etc., then it becomes 12 hours. In place of a surplus time of 3, I have created one of 12. This is why capital solicits the increase of population; and the very process by means of which necessary labour is reduced makes it possible to put new necessary labour (and hence surplus labour) to work. (I.e. the *production of workers* becomes cheaper, more workers can be produced in the same time, in proportion as *necessary labour time* becomes smaller or the time required for the *production of living labour capacity* becomes relatively smaller. These are identical statements.) (This still without regard to the fact that the increase in population increases the productive force of labour, since it makes possible a greater division and combination of labour etc. The increase of population is a *natural force* of labour, for which nothing is paid. From this standpoint, we use the term *natural force* to refer to the *social force*. All *natural forces of social labour* are themselves historical products.) It is, on the other side, a tendency of capital – just as in the case of the single working day – to reduce the many simultaneous necessary working days (which, as regards their value, can be taken as *one* working day) to the minimum, i.e. to posit as many as possible of them as *not necessary*. Just as in the previous case of the single working day it was a tendency of capital to reduce the necessary working hours, so now the necessary working days are reduced in relation to the total amount of objectified labour time. (If 6 are necessary to produce 12 superfluous working hours, then capital works towards the reduction of these 6 to 4. Or 6 working days can be regarded as one working day of 72 hours; if necessary labour time is reduced by 24 hours, then two days of necessary labour fall away – i.e. 2 workers.) At the same time, the newly created surplus capital can be realized as such only by being again exchanged for living labour. Hence the tendency of capital simultaneously to increase the *labouring population* as well as to reduce constantly its *necessary* part (constantly to posit a part of it as reserve). And the increase of population itself the chief means for reducing the necessary part. *At bottom this is only an application of the relation of the single working day*. Here already lie, then, all the contradictions which modern population theory expresses as such, but does not grasp. Capital, as the positing of surplus labour, is equally and in the same moment the positing and the not-positing of necessary labour; it exists only in so far as necessary labour both exists and does not exist. *

If the relation of the necessary working days to the total number of objectified working days was = 9:12 (hence surplus labour = 1/4), then the striving of capital is to reduce it to 6:9 (i.e. 2/3, hence surplus labour = 1/3). (Develop this more closely later; still, the major basic traits here, where we are dealing with the general concept of capital.)

* It does not belong here, but can already be recalled here, that the creation of surplus labour on the one side corresponds to the creation of minus-labour, relative idleness (or *not-productive* labour at best), on the other. This goes without saying as regards capital itself; but holds then also for the classes with which it shares; hence of the paupers, flunkeys, lickspittles etc. living from the surplus product, in short, the whole train of retainers; the part of the *servant* [*dienenden*] class which lives not from capital but from revenue. Essential difference between this *servant* class and the *working* class. In relation to the whole of society, the creation of *disposable time* is then also creation of time for the production of science, art etc. The course of social development is by no means that because one individual has satisfied his need he then proceeds to create a superfluity for himself; but rather because one individual or class of individuals is forced to work more than required for the satisfaction of its need – because *surplus labour* is on one side, therefore not-labour and surplus wealth are posited on the other. In reality the development of wealth exists only in these opposites [*Gegensätze*]: in potentiality, its development is the possibility of the suspension of these opposites. [18] Or because an individual can satisfy *his own* need only by simultaneously satisfying the need of and providing a surplus above that for *another* individual. This brutal under slavery. Only under the conditions of wage labour does it

lead to *industry, industrial* labour. – Malthus therefore quite consistent when, along with surplus labour and surplus capital, he raises the demand for surplus idlers, consuming without producing, or the necessity of waste, luxury, lavish spending etc.

Transition from the process of the production of capital into the process of circulation. – Devaluation of capital itself owing to increase of productive forces. (Competition.) (Capital *as unity and contradiction of production process and realization process.) Capital as barrier to production. – Overproduction. (Demand by the workers themselves.) – Barriers to capitalist production*

We have now seen how, in the *realization process,* capital has (1) maintained its value by means of exchange itself (exchange that is, with living labour); (2) increased, created a surplus value. There now appears, as the result of this unity of the process of production and the process of realization, the product of the process, i.e. capital itself, emerging as product from the process whose presupposition it was – as a product which is a value, or, *value* itself appears as the product of the process, and specifically a *higher value,* because it contains more objectified labour than the value which formed the point of departure. This value as such is *money.* However, this is the case only *in itself;* it is not posited as such; that which is *posited* at the outset, which is on hand, is a commodity with a certain (ideal) price, i.e. which exists only ideally [*ideell*] as a certain sum of money, and which first has to *realize* itself [*sich realisieren*] as such in the exchange process, hence has to re-enter the process of simple circulation in order to be posited as *money.* We now come therefore to the *third side of the process* in which capital is posited as such.

(3) Looked at precisely, that is, the *realization process* of capital – and money becomes capital only through the realization process – appears at the same time as its *devaluation process* [*Entwertungsprozess*], its demonetization. And this in two respects. First, to the extent that capital does not increase absolute labour time but rather decreases the relative, necessary labour time, by increasing the force of production, to that extent does it reduce the costs of its own production – in so far as it was presupposed as a certain sum of commodities, reduces its exchange value: one part of the capital on hand is constantly devalued owing to a decrease in the costs of production at which it can be *reproduced;* not because of a decrease in the amount of labour objectified in it, but because of a decrease in the amount of living labour which

it is henceforth necessary to objectify in this specific product. This constant devaluation of the *existing* capital does not belong here, since it already presupposes capital as completed. It is merely to be noted here in order to indicate how later developments are already contained in the general concept of capital. Belongs in the doctrine of the concentration and competition of capitals. – The *devaluation* being dealt with here is this, that capital has made the transition from the form of money into the form of a *commodity,* of a product, which has a certain price, which is to be *realized*. In its money form it existed as *value.* It now *exists* as product, and only ideally as price; but not as *value as* such. In order to *realize* itself, i.e. to maintain and to multiply itself as value, it would first have to make the transition from the form of money into that of use values (raw material – instrument – wages); but it would thereby lose the *form* of value; and it now has to enter anew into circulation in order to posit this form of general wealth anew. The capitalist now enters the process of circulation not simply as one engaged in exchange, but as *producer,* and the others engaged in exchange are, relative to him, *consumers.* They must exchange money in order to obtain his commodity for their consumption, while he exchanges his product to obtain their money. Suppose that this process breaks down – and the separation by itself implies the possibility of such a miscarriage in the individual case – then the capitalist’s money has been transformed into a worthless product, and has not only not gained a new value, but also lost its original value. But whether this is so or not, in any case devaluation forms one moment of the realization process; which is already simply implied in the fact that the product of the process in its immediate form is not *value,* but first has to enter anew into circulation in order to be realized as such. Therefore, while capital is reproduced as value and new value in the production process, it is at the same time posited as *not-value,* as something which first has to be *realized as value by means of exchange.* The three processes of which capital forms the unity are external; they are separate in time and space. As such, the transition from one into the other, i.e. their unity as regards the individual capitalists, is accidental. Despite their *inner unity,* they exist *independently* alongside one another, each as the presupposition of the other. Regarded broadly and as a whole, this inner unity must necessarily maintain itself to the extent that the whole of production rests on capital, and it must therefore realize all the necessary moments of its self-formation, and must contain the determinants necessary to make these moments real. But at the point we have reached so far, capital still does not appear as the determinant of circulation (exchange) itself but merely as one moment of the latter, and it appears to stop being capital just at the point where it enters into circulation. As a *commodity,* capital now shares the fate of commodities in general; it is a matter of accident whether or not it is exchanged for money, whether its *price* is realized or not.

In the production process itself – where capital continued to be presupposed as value – its *realization* appeared totally dependent solely on the relation of itself as objectified labour to living labour; i.e. on the relation of capital to wage labour. But now, as a product, as a commodity, it appears dependent on circulation, which lies outside this process. (In fact, as we have seen, it returns into it as its ground, but also and equally emerges from it again.) [19] As a commodity, it must be (1) a use value and, as such, an object of need, object of consumption; (2) it must be exchanged for its equivalent – in money. The new value can be realized only through a sale.

If it contained objectified labour at a price of 100 thalers before, and now at a price of 110 (the price here merely an expression, in money, of the amount of objectified labour), then this has to be demonstrated through the exchange of the labour objectified in the newly produced commodity for 110 thalers. The product is devalued [*entwertet*] initially in so far as it must be exchanged for money at all, in order to obtain its form as value again. Inside the production process, realization appeared totally identical with the production of surplus labour (the objectification of surplus time), and hence appeared to have no *bounds* other than those partly presupposed and partly posited within this process itself, but which are always posited within it as *barriers* to be forcibly overcome. There now appear barriers to it which lie *outside* it. To begin with, even on an entirely superficial inspection, the commodity is an exchange value only in so far as it is at the same time a *use value,* i.e. an object of consumption (still entirely irrelevant here, what kind of consumption); it ceases to be an exchange value when it ceases to be a use value (since it does not yet exist as money again, but rather still in a specific mode of existence coinciding with its natural quality). Its first barrier, then, is *consumption itself* – the *need for it.*

(Given the present presuppositions, there is no basis whatever for speaking of ineffective, *non-paying needs;* i.e. a need which does not itself possess a commodity or money to give in exchange.) Then, secondly, there has to be an equivalent for it, and, since circulation was presupposed at the outset as a constant magnitude – as having a given volume – but since, on the other hand, capital has created a new value in the production process, it seems indeed as if no equivalent were available for it. Thus, by emerging from the production process and re-entering circulation, capital (a) as *production,* appears to encounter a barrier in the available magnitude of *consumption* – of *consumption capacity.* As a specific use value, its quantity is irrelevant up to a certain point; then, however, at a certain level – since it satisfies only a specific need – it ceases to be required for consumption. As a *specific, one-sided, qualitative* use value, e.g. grain, its quantity itself is irrelevant only up to a certain level; it is required only in a specific quantity; i.e. in a certain *measure.* This measure, however, is given partly in its quality as use value – its *specific* usefulness, applicability – partly in the number of individuals engaged in exchange who have a need for this specific consumption. The number of consumers multiplied by the magnitude of their need for this *specific* product. Use value in itself does not have the boundlessness of value as such. Given objects can be consumed as objects of needs only up to a certain level. For example: No more than a certain amount of grain is consumed etc. Hence, as *use value,* the product contains a barrier – precisely the barrier consisting of the need for it – which, however, is measured not by the need of the producers but by the total need of all those engaged in exchange. Where the need for a certain use value ceases, it ceases to be a use value. It is measured as a use value by the need for it. But as soon is it ceases to be a use value, it ceases to be an object of circulation (in so far as it is not money). (b) As *new value* and as *value* as such, however, it seems to encounter a barrier in the magnitude of *available equivalents,* primarily money, not as medium of circulation but as money. The surplus value (distinct, obviously, from the original value) requires a surplus equivalent. This now appears as a second barrier.

(c) Money – i.e. wealth as such, i.e. wealth existing in and because of the exchange for *alien objectified labour* – originally appeared to collapse into itself [*in sich zusammenzufallen*] to the extent that it did not proceed to the exchange for *alien living labour,* i.e. to the production process. Circulation was incapable of renewing itself from within itself. At the same time, the production process now appears to be in a fix, in as much as it is not able to make the transition into the process of circulation. Capital, as production resting on wage labour, presupposes circulation as the necessary condition and moment of the entire motion. This specific form of production presupposes this specific form of exchange which finds its expression in the circulation of money. In order to renew itself, the entire product has to be transformed into money; not as in earlier stages of production, where exchange is by no means concerned with production in its totality, but only with superfluous production and superfluous products.

These are, then, the contradictions which present themselves of their own accord to a simple, objective, non-partisan view. How they are constantly suspended in the system of production resting on capital, but also constantly created again – and are suspended only by force (although this suspension appears up to a certain point merely as a quiet equilibration) – this is another question. The important thing at present is to take note of the existence of these contradictions. All the contradictions of circulation come to life again in a new form. The product as use value is in contradiction with itself as value; i.e. in as much as it exists in a specific quality, as a specific thing, as a product of specific natural properties, as a substance of need in contradiction with its substance as value, which it possesses exclusively on account of its being *objectified labour.* But this time, this contradiction is posited not merely as it was in circulation, as a *merely formal difference*; rather the quality of being measured by use value is here firmly determined as the quality of being measured by the total requirement for this product by all those engaged in exchange – i.e. by the amount of total consumption. The latter here appears as *measure* for it as use value and hence also as *exchange value.* In simple circulation it had simply to be transposed from the form of a particular use value into the form of exchange value. Its barrier then appeared only in the fact that, [coming] from circulation, it existed in a particular form owing to its *natural composition,* rather than in the value form in which it could be exchanged for all other commodities directly. What is posited now is that the *measure* of its availability is given in its *natural composition* itself. In order to be transposed into the general form, the use value has to be present in a limited and specific quantity; a *quantity* whose *measure* does not lie in the amount of *labour objectified in it,* but arises from its *nature as use value,* in particular, *use value for others.* At the same time, the previous contradiction, that money for-itself [*das für sich seiende Geld*] had to proceed to exchange itself for living labour, now appears even greater, in as much as the surplus money, in order to exist as such, or the surplus value, has to exchange itself for surplus value. Hence, as value, it encounters its barrier in alien production, just as, as use value, its barrier is alien consumption; in the latter, its measure is the amount of need for the specific product, in the former, the amount of *objectified labour* existing in circulation. The indifference of value as such towards use value is thereby brought into just as false a position [*Position*] as are, on the other side, the substance of value and its measure as objectified labour in general. *

> * The transition to the relation of supply, demand, prices cannot be made yet, as their development proper presupposes capital. Should not demand and, supply, in so far as they are abstract categories and do not yet express any particular economic relations, perhaps be examined already together with simple circulation or production?

The main point here – where we are concerned with the general concept of capital – is that it is this *unity of production and realization,* not *immediately* but only as a *process,* which is linked to certain conditions, and, as it appeared, *external* conditions. *

> * We saw earlier that the capital realization process presupposes the prior development of the *simple production process.* [20] This will be the case with *demand and supply* as well, to the extent that simple exchange presupposes a need for the product. The (direct) producer's *own* need as the need for others' demand. In the course of this development itself it will be seen what has to be presupposed to it, and all this is then to be thrown into the first chapters.

The creation by capital of *absolute surplus value* – more objectified labour – is conditional upon an expansion, specifically a constant expansion, of the sphere of circulation. The *surplus value* created at one point requires the creation of surplus value at *another* point, for which it may be exchanged; if only, initially, the production of more gold and silver, more money, so that, if surplus value cannot directly become capital again, it may exist in the form of money as the possibility of new capital. A precondition of production based on capital is therefore *the production of a constantly widening sphere of circulation,* whether the sphere itself is directly expanded or whether *more points within it are created as points of production.* While circulation appeared at first as a constant magnitude, it here appears as a moving magnitude, being expanded by production itself. Accordingly, it already appears as a moment of production itself. Hence, just as capital has the tendency on one side to create ever more surplus labour, so it has the complementary tendency to create more points of exchange; i.e., here, seen from the standpoint of *absolute* surplus value or surplus labour, to summon up more surplus labour as complement to itself; i.e. at bottom, to propagate production based on capital, or the mode of production corresponding to it. The tendency to create the *world market* is directly given in the concept of capital itself. Every limit appears as a barrier to be overcome. Initially, to subjugate every moment of production itself to exchange and to suspend the production of direct use values not entering into exchange, i.e. precisely to posit production based on capital in place of earlier modes of production, which appear primitive [*naturwüchsig*] from its standpoint. *Commerce* no longer appears here as a function taking place between independent productions for the exchange of their excess, but rather as an essentially all-embracing presupposition and moment of production itself. *

> * Of course, all production aimed at direct use value decreases the number of those engaged in exchange, as well as the sum of exchange values thrown into circulation, and above all the production of surplus values. Hence the tendency of capital (1) continually to enlarge the periphery of circulation; (2) to transform it at all points into production spurred on by capital. [21]

On the other side, the production of *relative surplus value,* i.e. production of surplus value based on the increase and development of the productive forces, requires the production of new consumption; requires that the consuming circle within circulation expands as did the productive circle previously. Firstly quantitative expansion of existing consumption; secondly: creation of new needs by propagating existing ones in a wide circle; *thirdly:*

production of *new* needs and discovery and creation of new use values. In other words, so that the surplus labour gained does not remain a merely quantitative surplus, but rather constantly increases the circle of qualitative differences within labour (hence of surplus labour), makes it more diverse, more internally differentiated. For example, if, through a doubling of productive force, a capital of 50 can now do what a capital of 100 did before, so that a capital of 50 and the necessary labour corresponding to it become free, then, for the capital and labour which have been set free, a new, qualitatively different branch of production must be created, which satisfies and brings forth a new need. The value of the old industry is preserved by the creation of the fund for a new one in which the relation of capital and labour posits itself in a *new* form. Hence exploration of all of nature in order to discover new, useful qualities in things; universal exchange of the products of all alien climates and lands; new (artificial) preparation of natural objects, by which they are given new use values. * The exploration of the earth in all directions, to discover new things of use as well as new useful qualities of the old; such as new qualities of them as raw materials etc.; the development, hence, of the natural sciences to their highest point; likewise the discovery, creation and satisfaction of new needs arising from society itself; the cultivation of all the qualities of the social human being, production of the same in a form as rich as possible in needs, because rich in qualities and relations – production of this being as the most total and universal possible social product, for, in order to take gratification in a many-sided way, he must be capable of many pleasures [*genussfähig*], hence cultured to a high degree – is likewise a condition of production founded on capital. This creation of new branches of production, i.e. of qualitatively new surplus time, is not merely the division of labour, but is rather the creation, separate from a given production, of labour with a new use value; the development of a constantly expanding and more comprehensive system of different kinds of labour, different kinds of production, to which a constantly expanding and constantly enriched system of needs corresponds.

> * The role played by *luxury* in antiquity in contrast to its role among the moderns, to be alluded to later.

Thus, just as production founded on capital creates universal industriousness on one side – i.e. surplus labour, value-creating labour – so does it create on the other side a system of general exploitation of the natural and human qualities, a system of general utility, utilizing science itself just as much as all the physical and mental qualities, while there appears nothing *higher in itself,* nothing legitimate for itself, outside this circle of social production and exchange. Thus capital creates the bourgeois society, and the universal appropriation of nature as well as of the social bond itself by the members of society. Hence the great civilizing influence of capital; its production of a stage of society in comparison to which all earlier ones appear as mere *local developments* of humanity and as *nature-idolatry.* For the first time, nature becomes purely an object for humankind, purely a matter of utility; ceases to be recognized as a power for itself; and the theoretical discovery of its autonomous laws appears merely as a ruse so as to subjugate it under human needs, whether as an object of consumption or as a means of production. In accord with this tendency, capital drives beyond national barriers and prejudices as much as beyond nature worship, as well as all traditional, confined, complacent, encrusted satisfactions of present needs, and reproductions of old ways of life. It is destructive towards all of this, and constantly revolutionizes it, tearing down all the barriers which hem in the development of the forces of production, the expansion of needs, the all-sided development of production, and the exploitation and exchange of natural and mental forces.

But from the fact that capital posits every such limit as a barrier and hence gets *ideally* beyond it, it does not by any means follow that it has *really* overcome it, and, since every such barrier contradicts its character, its production moves in contradictions which are constantly overcome but just as constantly posited. Furthermore. The universality towards which it irresistibly strives encounters barriers in its own nature, which will, at a certain stage of its development, allow it to be recognized as being itself the greatest barrier to this tendency, and hence will drive towards its own suspension.

Those economists who, like Ricardo, conceived production as directly identical with the self-realization of capital – and hence were heedless of the barriers to consumption or of the existing barriers of circulation itself, to the extent that it must represent counter-values at all points, having in view only the development of the forces of production and the growth of the industrial population – supply without regard to demand – have therefore grasped the positive essence of capital more correctly and deeply than those who, like Sismondi, emphasized the barriers of consumption and of the available circle of counter-values, although the latter has better grasped the limited nature of production based on capital, its negative one-sidedness. The former more its universal tendency, the latter its particular restrictedness. The whole dispute as to whether *overproduction* is possible and necessary in capitalist production revolves around the point whether the process of the realization of capital within production directly posits its realization in circulation; whether its realization posited in the *production process* is its *real* realization. Ricardo himself, of course, has a suspicion that the *exchange value* of a commodity is not a value apart from exchange, and that it proves itself as a value only in exchange; but he regards the barriers which production thereby encounters as accidental, as barriers which are overcome. He therefore conceives the overcoming of such barriers as being in the essence of capital, although he often becomes absurd in the exposition of that view; while Sismondi, by contrast, emphasizes not only the encounter with the barriers, but their creation by capital itself, and has a vague intuition that they must lead to its breakdown. He therefore wants to put up barriers to production, from the outside, through custom, law etc., which of course, as merely external and artificial barriers, would necessarily be demolished by capital. On the other side, Ricardo and his entire school never understood the really *modern crises,* in which this contradiction of capital discharges itself in great thunderstorms which increasingly threaten it as the foundation of society and of production itself.

The attempts made from the orthodox economic standpoint to deny that there is *general overproduction* at any given moment are indeed childish. Either, in order to rescue production *based on capital* (see e.g. MacCulloch), [22] all its specific qualities are ignored and their specific character as forms omitted, and capital is conceived as its inverse, as simple production for *immediate use value.* Totally abstracts away the essential relations. In fact, in order to cleanse it of contradictions, it is virtually dropped and negated. [23] – Or, like e.g. Mill, more perceptively (copied from the dull Say): *supply* and *demand* are allegedly identical, and should therefore necessarily correspond.

[24] Supply, namely, is allegedly a demand measured by its own amount. Here a great confusion: (1) This identity of supply, so that it is a demand measured by its own amount, is true only to the extent that it is *exchange value* = to a certain amount of objectified labour. To that extent it is the measure of its own demand – as far as *value* is concerned. But, as such a value, it first has to be realized through the exchange for *money,* and as object of exchange for money it depends (2) on its *use value,* but as use value it depends on the mass of needs present for it, the demand for it. But as use value it is absolutely not measured by the labour time objectified in it, but rather a measuring rod is applied to it which lies outside its nature as exchange value. Or, it is further said: *Supply itself is demand for a certain product* of a *certain value* (which expresses itself in the demanded amount of the product). Then, if the supplied product is unsaleable, it proves that too much has been produced of the supplied commodity and too little of what the supplier demands. Thus allegedly there is no general overproduction, but merely overproduction of one or a few articles, as against underproduction of others. This again forgets that what the producing capital demands is not a specific use value, but *value* for itself, i.e. money – money not in the role of medium of circulation, but as a general form of wealth, or a form of the realization of capital in one regard, a return to its original dormant state in the other. But the assertion that too little *money* is produced means indeed nothing else than what is being asserted, that production is not identical with realization, i.e. that it is *overproduction,* or, what is the same, that it is production which cannot be transformed into money, into *value;* production which does not pass the test of circulation. Hence the illusion of the money-artists (including Proudhon etc.), that it is a case of lack of *means of circulation* – on account of the high cost of money – and that more money has to be created artificially. [25] (See also the Birminghamites, e.g. the *Gemini*.) [26] Or it is said that *production and consumption* are the same *from the social standpoint,* that hence an excess or disproportion between the two can never take place. Social standpoint here means the abstraction which ignores precisely the specific social structure and relations and hence also the contradictions which emerge from it. Storch, for example, remarked quite correctly against Say that a great part of consumption is not consumption for immediate use, but consumption in the production

process, e.g. consumption of machines, coal, oil, required buildings etc. [27] This consumption is in no way identical with that at issue here. Malthus and Sismondi have likewise correctly remarked that e.g. the workers' consumption is in no way in itself a *sufficient* consumption for the capitalist. [28] The moment of realization is here simply thrown out entirely, and production and consumption are simply equated, i.e. not production based on capital but production based directly on *use value* is presupposed. Or, expressed *socialistically*: [29] labour and the exchange of labour, i.e. production and its exchange (circulation), are allegedly the entire process; how then could a disproportion arise except by oversight, miscalculation? Labour is here regarded not as wage labour, nor capital as capital. On one side, the consequences of production based on capital are accepted, on the other side the presuppositions and conditions of these consequences are denied – necessary labour as posited by and for surplus labour. Or – e.g. Ricardo – since production is itself regulated by the costs of production, it allegedly regulates itself, and if one branch of production does not realize itself then capital withdraws from it to a certain degree and throws itself on another point where it is needed. [30] But apart from the fact that this necessity of evening-up already *presupposes* the unevenness, the disharmony and hence the contradiction – in a general crisis of overproduction the contradiction is not between the different kinds of productive capital, but between industrial and loanable capital – between capital as directly involved in the production process and capital as money existing (relatively) outside of it. Finally: *proportionate production* (this is already in Ricardo also, etc.) only when it is capital's tendency to distribute itself in correct proportions, but equally its necessary tendency – since it strives limitlessly for surplus labour, surplus productivity, surplus consumption etc. – to drive beyond the proportion. (In *competition* this inner tendency of capital appears as a compulsion exercised over it by *alien capital,* which drives it forward beyond the correct proportion with a constant *march, march!* Free competition, as Mr Wakefield correctly sniffs out in his commentary on Smith, has *never yet* been developed by the economists, no matter how much they prattle about it, and [no matter] how much it is the basis of the entirety of bourgeois production, production resting on capital. [31] It has been understood only negatively: i.e. as negation of monopolies, the guild system, legal regulations etc. As negation of feudal production. But it also has to be something *for itself,* after all, since a mere 0 is an empty negation, abstraction, from a barrier which immediately arises again e.g. in the form of monopoly, natural monopolies etc. Conceptually, *competition* is nothing other than the inner *nature of capital,* its essential character, appearing in and realized as the reciprocal interaction of many capitals with one another, the inner tendency as external necessity.) (Capital exists and can only exist as many capitals, and its self-determination therefore appears as their reciprocal interaction with one another.) Capital is just as much the constant positing as the suspension of *proportionate production.* The existing proportion always has to be suspended by the creation of surplus values and the increase of productive forces. But this demand, that production should be expanded *simultaneously* and *at once in the same proportion,* makes external demands upon capital which in no way arise out of it itself; at the same time, the departure from the given proportion in one branch of production drives all of them out of it, and in unequal proportions. So far (for we have not yet reached the aspect of capital in which it is *circulating capital,* and still have circulation on one side and capital on the other, or production as its presupposition, or ground from which it arises), even from the standpoint of production alone, circulation contains the relation to consumption and production – in other words, surplus labour as counter value [*Gegenwert*], and differentiation of labour in an ever richer form.

The simple concept of capital has to contain its civilizing tendencies etc. *in themselves;* they must not, as in the economics books until now, appear merely as external consequences. Likewise the contradictions which are later released, demonstrated as already latent within it.

So far in the realization process, we have only the indifference of the individual moments towards one another; that they determine each other internally and search for each other externally; but that they may or may not find each other, balance each other, correspond to each other. The inner necessity of moments which belong together, and their indifferent, independent existence towards one another, are already a foundation of contradictions.

Still, we are by no means finished. The contradiction between production and realization – of which capital, by its concept, is the unity – has to be grasped more intrinsically than merely as the indifferent, seemingly reciprocally independent appearance of the individual moments of the process, or rather of the totality of processes.

To approach the matter more closely: *First of all, there is a limit, not inherent to production generally, but to production founded on capital.* This limit is double, or rather the same regarded from two directions. It is enough here to demonstrate that capital contains a *particular* restriction of production – which contradicts its general tendency to drive beyond every barrier to production – in order to have uncovered the foundation of *overproduction,* the fundamental contradiction of developed capital; in order to have uncovered, more generally, the fact that capital is not, as the economists believe, the *absolute* form for the development of the forces of production – not the absolute form for that, nor the form of wealth which absolutely coincides with the development of the forces of production. The stages of production which precede capital appear, regarded from its standpoint, as so many fetters upon the productive forces. It itself, however, correctly understood, appears as the condition of the development of the forces of production as long as they require an external spur, which appears at the same time as their bridle. It is a discipline over them, which becomes superfluous and burdensome at a certain level of their development, just like the guilds etc. These inherent limits have to coincide with the nature of capital, with the essential character of its very concept. These necessary limits are:

(1) *Necessary labour* as limit on the exchange value of living labour capacity or of the woes of the industrial population;

(2) *Surplus value* as limit on surplus labour time; and, in regard to relative surplus labour time, as barrier to the development of the forces of production;

(3) What is the same, the *transformation into money,* exchange value as such, as limit of production; or exchange founded on value, or value founded on exchange, as limit of production. This is:

(4) again the same as *restriction of the production of use values by exchange value;* or that real wealth has to take on a *specific* form distinct from itself, a form not absolutely identical with it, in order to become an object of production at all.

However, these limits come up against the *general tendency of capital* (which showed itself in simple circulation, where money as medium of circulation appeared as merely vanishing, without independent necessity, and hence not as limit and barrier) to forget and abstract from:

(1) necessary labour as limit of the exchange value of living labour capacity; (2) surplus value as the limit of surplus labour and development of the forces of production; (3) money as the limit of production; (4) the restriction of the production of use values by exchange value.

Hence overproduction: i.e. the sudden *recall* of all these necessary moments of production founded on capital; hence general devaluation in consequence of forgetting them. Capital, at the same time, [is] thereby faced with the task of launching its attempt anew from a higher level of the development of productive forces, with each time greater collapse *as capital.* Clear, therefore, that the higher the development of capital, the more it appears as barrier to production – hence also to consumption – besides the other contradictions which make it appear as burdensome barrier to production and intercourse.

<The entire *credit system,* and the over-trading, over-speculation etc. connected with it, rests on the necessity of expanding and leaping over the barrier to circulation and the sphere of exchange. This appears more colossally, classically, in the relations between peoples than in the relations between individuals. Thus e.g. the English forced to *lend* to foreign nations, in order to have them as customers. At bottom, the English capitalist exchanges doubly with *productive* English capital, (1) as himself, (2) as Yankee etc. or in whatever other form he has placed his money.>

<Capital as *barrier to production* is pointed out: e.g. Hodgskin: [32] ‘In the present state, every accumulation of capital adds to the amount of profit demanded from the labourer, and extinguishes all that labour which would only procure the labourer his comfortable existence ... *Profit* the limitation of production.’ (H[odgskin, Notebook,] p. 46.) [33] Through foreign trade, the barrier of the sphere of exchange [is] expanded, and [it is] made possible for the capitalist to consume more surplus labour: ‘In a series of years the world can take no more from us than we can take from the world. Even the profits made by our merchants in their foreign trade are paid by the consumer of the return goods here. Foreign trade mere barter, and as such exchange for the convenience and enjoyment of the capitalist. But he can consume commodities

to a certain degree only. He exchanges cottons etc. for the wines and silks of foreign countries. But these *represent only the surplus labour of our own population* as much as the clothes and cottons, and in this way the *destructive power of the capitalist is increased beyond all bounds.* Thus nature is *outwitted.' (Source and Remedy* etc., pp. 27, 28.) [34] How the *glut* is connected with the *barrier* of necessary labour: 'The very meaning of an increased demand by the labourers is, a disposition to take less themselves, and leave a larger share for their employers; and if it be said that this, *by diminishing consumption, increases glut,* I can only say that *glut then is synonymous with high profits.' (Enquiry,* London, 1821, p. 12.) [35] Herein the one side of the contradiction completely expressed. 'The practice of stopping labour at that point where it can produce, in addition to the subsistence of the labourer, a profit for the capitalist, opposed to the natural law which regulates production.' (H[odgskin, Notebook,] 41, IX.) [36] 'The more the capital accumulates, the more the *whole amount of profit demanded does so;* so there arises an *artificial check* to production and population.' (H[odgskin, Notebook,] 46.) [37] The contradictions between capital as instrument of production in general and as instrument of production of value, developed as follows by Malthus (X, 40 seq.): 'Profits are invariably measured by *value* and never by *quantity* ... The *wealth* of a country depends partly upon the *quantity of produce* obtained by its labour, and partly upon *such an adaptation of this quantity to the wants and powers of the existing population* as is calculated to give it value. Nothing can be more certain than that it is not determined by either of them alone. But where wealth and value are perhaps the most nearly connected, is in *the necessity of the latter to the production of the former.* The value set upon commodities, that is the sacrifice of labour which people are willing to make in order to sustain them, in the actual state of things may be said to be *almost the sole cause* of the existence of wealth ... The consumptive demand occasioned only by the workmen employed in productive labour can never *alone* furnish a motive to the accumulation and employment of capital ... *the powers of production alone do not secure the creation of a proportionate degree of wealth,* as little as the *increase of population.* What it requires in addition is *such a distribution of produce,* and such an adaptation of this produce to the wants of those who are to consume it, as constantly to increase *the exchangeable value of the whole mass,* i.e. the powers of production are only called fully into motion by the unchecked demand for all that is produced ... [38] This is however brought about on the one hand by constantly new branches of industry (and *reciprocal* expansion of the old), by means of which the old obtain new *markets* etc. Production indeed itself creates demand, in that it employs more workers in the same branch of business, and creates new branches of business, where new capitalists again employ new workers and at the same time alternately become market for the old; but the demand created by the productive labourer himself can never be an *adequate* demand, because it does not go to the full extent of what he produces. If it did, there would be no profit, consequently no motive to employ him. The very existence of a profit upon any commodity presupposes *a demand exterior to that of the labourer who has produced it.*' 'Both labourers and capital may be redundant compared with the means of employing them profitably.'> [39]

<To be noted for (3), to which we shall soon proceed, that the provisional accumulation, as which capital appears *vis-à-vis* labour, and by means of which it is the command over labour, is at first nothing else but *surplus labour* itself in the form of *surplus produce,* at the same time *claim on alien co-existing labour.>*

The point here, of course, is not yet to develop overproduction specifically, but only the predisposition to it, such as it is posited in primitive form in the capital relation itself. We must also, therefore, omit here any regard for the other possessing and consuming etc. classes, which do not produce but live from their revenue, hence exchange with capital; form centres of exchange for it. We can consider them only partly (but better, along with *accumulation*), in so far as they are most important for the historic formation of capital.

In production based on slavery, as well as in patriarchal agricultural-industrial production, where the greatest part of the population directly satisfies the greatest part of its needs directly by its labour, the sphere of circulation and exchange is still very narrow; and more particularly in the former, the slave does not come into consideration as *engaged in exchange* at all. But in production based on capital, consumption is mediated at all points by exchange, and labour never has a *direct* use value for those who are working.

Its entire basis is labour as exchange value and as the creation of exchange value.

Well. First of all

the wage worker as distinct from the slave is himself an independent centre of circulation, someone who exchanges, posits exchange value, and maintains exchange value through exchange. *Firstly:* in the exchange between that part of capital which is specified as wages, and living labour capacity, the *exchange value* of this part of capital is posited immediately, before capital again emerges from the production process to enter into circulation, or this can be conceived as itself still an act of circulation. *Secondly:* To each capitalist, the total mass of all workers, with the exception of his own workers, appear not as workers, but as consumers, possessors of exchange values (wages), money, which they exchange for his commodity. They are so many centres of circulation with whom the act of exchange begins and by whom the exchange value of capital is maintained. They form a proportionally very great part – although not quite so great as is generally imagined, if one focuses on the industrial worker proper – of all consumers. The greater their number – the number of the industrial population – and the mass of money at their disposal, the greater the sphere of exchange for capital. We have seen that it is the tendency of capital to increase the industrial population as much as possible.

Actually, the relation of one capitalist to the workers of *another* capitalist is none of our concern here. It only shows every capitalist's illusion, but alters nothing in the relation of capital in general to labour. Every capitalist knows this about his worker, that he does not relate to him as producer to consumer, and [he therefore] wishes to restrict his consumption, i.e. his ability to exchange, his wage, as much as possible. Of course he would like the workers of *other* capitalists to be the greatest consumers possible of *his own* commodity. But the relation of *every* capitalist to *his own* workers is the *relation as such* of *capital and labour,* the essential relation. But this is just how the illusion arises – true for the individual capitalist as distinct from all the others – that *apart from his* workers the whole remaining working class confronts him as *consumer* and *participant in exchange,* as money-spender, and not as worker. It is forgotten that, as Malthus says, 'the very existence of a profit upon any commodity pre-supposes a *demand exterior to that of the labourer who has produced it',* [40] and hence the *demand of the labourer himself can never be an adequate demand.* Since one production sets the other into motion and hence creates consumers for itself in the *alien* capital's workers, it *seems* to each individual capital that the demand of the working class posited by production itself is an 'adequate demand'. On one side, this demand which production itself posits drives it forward, and must drive it forward beyond the *proportion* in which it would have to produce with regard to the workers; on the other side, if the demand *exterior to the demand of the labourer himself* disappears or shrinks up, then the collapse occurs. Capital itself then regards *demand by the worker* – i.e. the payment of the wages on which this demand rests – not as a gain but as a loss. I.e. the *immanent relation between capital and labour* asserts itself. *Here again it is the competition among capitals,* their indifference to and independence of one another, which brings it about that the individual capital relates to the workers of the entire remaining capital *not as to workers:* hence is driven beyond the right proportion. What precisely distinguishes capital from the master-servant relation is that the *worker* confronts him as consumer and possessor of exchange values, and that in the form of the *possessor of money,* in the form of money he becomes a simple centre of circulation – one of its infinitely many centres, in which his specificity as worker is extinguished. *

> * It is quite the same with the demand created by production itself for raw material, semi-finished goods, machinery, means of communication, and for the auxiliary materials consumed in production, such as dyes, coal, grease, soap, etc. This effective, exchange-value-positing demand is adequate and sufficient as long as the producers exchange among themselves. Its inadequacy shows itself as soon as the final product encounters its limit in direct and final consumption. This *semblance,* too, which drives beyond the correct proportion, is founded in the essence of capital, which, as will be developed more closely in connection with competition, *is* something which repels itself, *is* many capitals mutually quite indifferent to one another. In so far as one capitalist *buys* from others, buys commodities, or sells, they are within the simple exchange relation; and do not relate to one another as capital. The *correct* (imaginary) proportion in which they must exchange with one another in order to realize themselves at the end as capital lies *outside* their relation to one another.

To begin with: capital forces the workers beyond necessary labour to surplus labour. Only in this way does it realize itself, and create surplus value. But on the other hand, it posits necessary labour only *to the extent* and *in so far as* it is surplus labour and the latter is *realizable* as *surplus value.* It posits surplus labour, then, as the condition of the necessary, and surplus value as the limit of objectified labour, of value as such. As soon as it cannot posit value, it does not posit necessary labour; and, given its foundation, it cannot be otherwise. It therefore restricts labour and the creation of value – by an artificial check, as the English express it – and it does so on the same grounds as and to the same extent that it posits surplus labour and surplus value. By its nature, therefore, it posits a *barrier* to labour and value-creation, in contradiction to its tendency to expand them boundlessly. And in as much as it both posits a barrier *specific* to itself, and on the other side equally drives over and beyond *every* barrier, it is the living contradiction. *

> * Since value forms the foundation of capital, and since it therefore necessarily exists only through exchange for *counter-value,* it thus necessarily repels itself from itself. A *universal capital,* one without alien capitals confronting it, with which it exchanges – and from the present standpoint, nothing confronts it but wage labourers or itself – is therefore a non-thing. The reciprocal repulsion between capitals is already contained in capital as realized exchange value.

While capital thus, on one side, makes surplus labour and its *exchange* for *surplus labour* into the precondition of necessary labour and hence of the positing of *labour capacity* [*Arbeitsvermögen*] as a centre of exchange – hence already narrows and attaches conditions to the sphere of exchange from this side – it is just as essential to it, on the other side, to restrict the worker's consumption to the amount necessary to reproduce his labour capacity – to make the value which expresses *necessary labour* the barrier to the realization of labour capacity and hence of the worker's *exchange capacity,* and to strive to reduce the relation of this necessary labour to surplus labour to the minimum. [Thus we have] a new barrier to the sphere of exchange, which is, however, at the same time identical, as is the first, with the tendency of capital to relate to every limit on its self-realization as to a barrier. The boundless enlargement of its value – boundless creation of value – therefore absolutely identical here with the positing of barriers to the sphere of exchange, i.e. the possibility of realization – the realization of the value posited in the production process.

The same with the *productive force.* On the one hand, the necessary tendency of capital to raise it to the utmost, in order to increase relative *surplus time.* On the other hand, thereby decreases *necessary labour time,* hence the worker's exchange capacity. Further, as we have seen, relative *surplus value* rises much more slowly than the force of production, and moreover this proportion grows ever smaller as the magnitude reached by the productive forces is greater. *But the mass of products grows in a similar proportion* – if not, then new capital would be set free – as well as labour – which did not enter into circulation. But to the same degree as the mass of products grows, so grows the difficulty of realizing the labour time contained in them – because the demands made on consumption rise. (We are still concerned here only with the way in which the capital *realization process* is its *devaluation process.* Out of place here would be the question how, while it has the tendency to *heighten the productive forces boundlessly,* it *also and equally* makes one-sided, limits etc. the *main force of production, the human being himself,* and has the tendency in general to restrict the forces of production.)

Capital, then, posits *necessary labour time* as the barrier to the exchange value of living labour capacity; *surplus labour time* as the barrier to necessary labour time; and *surplus value* as the barrier to surplus labour time; while at the same time it drives over and beyond all these barriers, to the extent that it posits *labour capacity* opposite itself as something simply engaged in exchange, as money, and surplus labour time as the only barrier, because creatrix of surplus value. (Or, from the first aspect, it posits the exchange of surplus values as the barrier to the exchange of the necessary values.)

In one and the same moment, it posits the *values on hand* in circulation – or, what is the same, the proportion of values posited by it to the values contained in it and *presupposed* in circulation – as the barrier, the necessary barrier to its value-creation; on the other hand, its productivity as the only barrier and creatrix of values. It therefore drives constantly on one side towards its own devaluation, on the other side towards the obstruction of the productive forces, and of labour which objectifies itself in values.

*Overproduction. – Proudhon (How is it possible that in the price of the commodity which the worker buys, he pays the profit etc. and still obtains his necessary wages). – Price of the commodity and labour time. Surplus etc. (*Price *and value etc.) – Capitalist does not sell* too dear; *but still above what the thing costs him. – Price (fractional). Bastiat. Decline of the fractional price. – Price can fall below value without damage to capital. Number and unit (measure) important in the multiplication of prices*

<This nonsense about the impossibility of overproduction (in other words, the assertion of the immediate identity of capital's process of production and its process of realization) has been expressed in a manner which is at least sophistical, i.e. ingenious, as mentioned above, [41] by James Mill, in the formula that supply = its own demand, that supply and demand therefore balance, which means in other words the same thing as that value is determined by labour time, and hence that *exchange adds nothing to it,* and which forgets only that exchange does have to take place and that this depends (in the final instance) on the *use value.* Mill says, then, that if demand and supply do not balance, this comes about because too much has been produced of one specific product (the supplied product) and too little of the other (the one in demand). This too much and too little concerns not the exchange value, but the use value. More of the supplied product exists than is 'needed'; this is what it boils down to. Hence that overproduction comes from use value and therefore from exchange itself. This in stultified form in Say – products are exchanged only for products; [42] therefore, at most, too much has been produced of one and too little of another. Forgetting: (1) that values are exchanged for values, and a product exchanges for another only to the extent that it is value; i.e. that it is or becomes money; (2) it exchanges for labour. The good gentleman adopts the standpoint of *simple exchange,* in which indeed no overproduction is possible, for it is indeed concerned not with exchange value but with use value. Overproduction takes place in connection with realization, not otherwise. [43]>

Proudhon, who certainly hears the bells ringing but never knows where, therefore sees the origin of overproduction in the fact 'that the worker cannot buy back his product’. [44] By this he understands that interest and profit are added on to it; or that the price of the product is an overcharge on top of its real value. This demonstrates first of all that he understands nothing about the determination of value, which, generally speaking, can include no overcharge. In practical commerce, capitalist A can screw capitalist B. The one pockets what the other loses. If we add them both together, then the sum of their exchange = the sum of the labour time objectified in it, of which capitalist A has merely pocketed more than his share in relation to B. From all the profits made by capital, i.e. the total mass of capitalists, there is deducted (1) the constant part of capital; (2) the wage, or, the amount of objectified labour time necessary in order to reproduce living labour capacity. They can therefore divide nothing among themselves other than the surplus value. The proportion – just or unjust – in which they distribute this surplus value among themselves alters absolutely nothing about exchange or about the exchange relation between capital and labour.

It might be said that *necessary labour time* (i.e. the wage), which therefore excludes profit, and is rather to be deducted from it, is itself again determined by the *prices* of products which already include profit. Where else could the profit come from which the capitalist who does not directly employ this worker makes in the exchange with him? For example, the spinner’s worker exchanges his wages for so many bushels of grain. But in the price of each bushel, the profit of the farmer, i.e. of capital, is already included. So that the *price* of the consumption goods which are bought by necessary labour itself already includes surplus labour time. It is clear, first of all, that the wage paid by the spinner to his workmen must be high enough to buy the necessary bushel of wheat, regardless of what profit for the farmer may be included in the *price* of the bushel of wheat; but that, likewise, on the other side, the wage which the farmer pays his workers must be high enough to procure for them the necessary quantity of clothing, regardless of what profit for the weaver and the spinner may be included in the *price* of these articles of clothing.

The puzzle arises simply because (1) *price* and *value* are being mixed up; (2) relations are brought in which are irrelevant to the determination of value of such. Suppose initially – and this is the conceptual relation – that capitalist A himself produces all the consumption goods which the worker needs, or which represent the sum of use values in which his necessary labour objectifies itself. Then, with the money which he obtains from the capitalist – money appears in this transaction only as medium of circulation – the worker would have to buy back from the capitalist, with that money, a fractional part – the part representing his necessary labour – of his product. The *price* of a fractional part of capitalist A's product is of course the same for the worker as for everyone else engaged in exchange. From the moment he buys from the capitalist, his specific quality as worker is extinguished; the money contains no trace of the relation in which, or of the operation by which, it was obtained; in circulation he confronts the capitalist simply as M, and the capitalist confronts him as C; as realizer of the *price* of C, which is hence presupposed for him just as for every other representative of M, i.e. buyer. Good. But in the price of the fractional part of the commodity which he buys, the profit is included in which the surplus value going to the capitalist appears. If his necessary labour time, therefore, represents 20 thalers = a certain fractional part of the product, it follows that, if the profit is 10%, the capitalist sells him the commodity for 22 thalers.

That is what Proudhon thinks, and concludes from it that the worker cannot buy back his product, i.e. the fractional part of the total product which objectifies his *necessary labour.* (We will come back directly to his other conclusion, that *therefore* capital cannot adequately exchange, *hence* overproduction.) To make the matter tangible, say that the worker's 20 thalers = 4 bushels of grain. Consequently – if 20 thalers is the value of the 4 bushels expressed in money – if the capitalist sells them for 22, then the worker could not buy back the 4 bushels, or rather he could buy only 3 7/11 bushels. In other words, he imagines that the monetary transaction distorts the relation. 20 thalers is the price of necessary labour = 4 bushels; and the capitalist pays this to the worker; but as soon as the latter presents his 20 thalers and asks for the 4 bushels, he gets only 3 7/11. Since he would thereby receive less than the *necessary* wage, he could not live at all, and thus Mr Proudhon proves more than he intends. *

---

* It is beside the point here that capital, in practice as well as in general tendency, directly employs *price,* as e.g. in the truck system, to defraud *necessary labour,* and to reduce it below the standard given by nature as well as by a specific state of society.

> We must always presuppose here that the wage paid is *economically* just, i.e. that it is determined by the general laws of economics. The contradictions have to follow here from the general relations themselves, and not from fraud by individual capitalists. The further forms which this assumes in reality belong in the doctrine of wages.

But the presupposition, if you please, is wrong. If 5 thalers expresses the *value* of a bushel, i.e. the labour time objectified in it, and if 4 bushels express the necessary wages of labour, then capitalist A sells these 4 bushels not, as Proudhon thinks, for 22 but for 20 thalers. But the thing is this: let the total product (including necessary and surplus labour time) equal 110 thalers = 22 bushels; let 16 of these bushels = 80 thalers, represent the capital invested in seed, machinery etc.; 4 bushels = 20 thalers for necessary labour time; 2 bushels = 10 thalers, surplus labour time. The capitalist sells each bushel at 5 thalers, the necessary value of the bushel, and nevertheless he makes a gain of 10% on each bushel, or 5/10 of a thaler, 1/2 a thaler = 15 silver groschen. How? Because he sells 22 × 5 instead of 20 × 5. We can here equate to 0 the additional capital he would have to lay out in order to produce 2 additional bushels, since these can dissolve in pure surplus labour, more thorough ploughing, elimination of weeds, procurement of mineral fertilizer which, say, costs him nothing, etc. The value contained in the 2 surplus bushels has cost *him nothing,* hence makes up a surplus above his expenditures. If he sells 20 of the 22 bushels for what they cost him, for 100 thalers, plus 2, which cost him nothing – but whose value = the labour contained in them – for 10 thalers, then it is the same for him as if he sold all of them, each bushel for 15 silver groschen more than it cost him. (For 1/2 a thaler or 10% of 5 thalers = 5/10.) Therefore, although he makes 2 thalers on the 4 bushels he sells to the worker, the worker obtains each bushel at its necessary value. The capitalist makes 2 thalers on them only because, beside these 4 bushels, he sells 18 additional ones at the identical price. If he sold only 16, he would make nothing; for then he would sell a total of: 5 × 20 =100, his invested capital.

Indeed, in manufacturing, too, it is possible that the capital’s outlays do not increase, while a surplus value is sold nevertheless; i.e. it is not necessary that the outlay in raw material and machinery should grow. Assume that the same product obtains a higher finish through labour by hand – the mass of required raw material and instrument held constant – and hence its use value, therefore the use value of the product, increases, not in quantity, but in quality, owing to the increased hand labour employed on it. Its exchange value – the labour objectified in it – simply grows in relation to this labour. If the capitalist then sells for 10% more, then the worker gets paid the fractional part of the product, expressed in money, which represents necessary labour; and if the product could be divided, then the worker could buy this fractional part. The capitalist's profit would come not from overcharging the worker for this fractional part, but from the fact that in the whole of the product he sells a fractional part which he has not paid for, and which represents, precisely, *surplus labour time.* The product is always divisible as value; in its natural form, it need not be so. Profit here always comes from the fact that the whole value contains a fractional part which is not paid, and hence a fractional part of surplus labour is paid in each fractional part of the whole. So in the above example. When the capitalist sells 22 bushels, i.e. 2 which represent surplus labour, it is the same as if he sold an extra 1/10 of a bushel per bushel, i.e. 1/10 surplus value. If e.g. only one clock has been produced, where the relation of labour, capital and surplus value is the same, then the quality of the clock has been raised 1/10 in value by 1/10 labour time which costs the capitalist nothing.

Third case, that the capitalist, as is usual in manufacturing (but not in extractive industry), needs more raw material (let the instrument remain constant; however, nothing is changed if it, too, is variable) in which the surplus labour time objectifies itself. (Actually this does not belong here yet, for capital here can or must just as well be assumed as having also produced the raw material, e.g. the cotton, and surplus production at any point has to reduce itself to *mere* surplus labour, or, what is rather the *reality,* presupposes *simultaneous* surplus labour at all points of circulation.) Assume that he spins up 25 lb. of cotton, which cost him 50 thalers, and for which he requires machinery (which we will assume to be entirely consumed in the production process) at 30 thalers, and wages 20 thalers, for 25 lb. of twist, which he sells at 110. He sells each pound of twist, then, for 4 2/5 thalers, or 4 thalers 12 silver groschen. The worker thus obtains 4 6/11 lb. of twist, if he wants to buy it again. If the worker were working for himself, he would likewise sell the pound for 4 thalers 12 silver groschen and make no profit – presupposing that he performs only the necessary labour; but he would spin up less cotton.

As we know, the value of a pound of twist consists exclusively of the amount of labour time objectified in it. Now suppose that the value of the pound of twist = 5 thalers. Given that 4/5, i.e. 4 thalers, represent cotton, instrument etc.; then 1 thaler represents the labour realized in the cotton by means of the instrument. If the worker, in order to live from spinning, needs say 20 thalers per month, then – since he earns 1 thaler for spinning 1 lb. of twist, but needs 20 – he would have to spin 20 lb. of twist. If he himself owned the cotton, material etc., and were working for himself, hence were his own master, then he would have to sell 20 lb. of twist; since he would earn only 1/5 on each, one thaler, and 1 × 20 = 20. If he works for the capitalist, then the labour which spins up 20 lb. of cotton only represents the necessary labour; for, by presupposition, of the 20 lb. of twist or 20 × 5 = 100 thalers, 80 thalers only represent the already purchased cotton and instrument, and the newly reproduced value represents nothing but *necessary labour.* Of the 20 lb. of twist, 4 lb. = 20 thalers would represent necessary labour, and 16 nothing more than the constant part of capital. 16 × 5 = 80 thalers. Each additional pound which the capitalist orders to be produced over and above the 20 contains 1/5 surplus labour, surplus value for him. (Objectified labour which he has sold without having paid for it.) If he orders 1 more pound spun, he gains 1 thaler; 10 lb, more, 10 thalers. Out of 10 lb. or 50 thalers, the capitalist would have 40 thalers to replace his investment and 10 thalers of surplus labour; or 8 lb. of twist with which to buy the material for 10 (machinery and cotton), and 2 lb. of twist, or their value, which have cost him nothing. If we now summarize the capitalist’s accounts, we find that he has invested, in thalers

		Wages	*Surplus value*
80 + 40 =	120 (raw material, instrument, etc.)	20	10
	120	20	10 = 150

Altogether he has produced 30 lb. of twist (30 × 5 = 150); the pound at 5 thalers, the exact *value* of the pound, i.e. purely determined by the labour objectified in it, and deriving value only from the latter. Of this 30 lb., 24 represent constant capital, 4 lb. go for wages, and 2 form the *surplus value*. Calculating it on the basis of his total investment, 140 thalers or 28 lb., as the capitalist himself does, this surplus value forms 1/14 = 7 1/7% (although, in the example given, the surplus value amounts to 50% on labour).

Now assume that the productivity of labour grows to the extent that he is capable of spinning 40 lb. with the same wage cost. According to our assumption he would sell these 40 lb. at their real value, i.e. the pound at 5 thalers, of which 4 thalers is labour objectified in cotton etc., 1 thaler is newly added labour. He would then sell:

40 lb. - the lb. @ 5 thalers = 40 × 5 = 200; from these 40 lb., deduct

20 lb. for necessary labour	= 100	
	100	On the first 20 lb. he would have made not a farthing; of the remaining hundred, take off 4/5 = 4 × 20 = 80.
	80	for material, etc.
		Leaves:
	20	thalers

On an investment of 200 thalers the capitalist would have earned 20, or 10%. 10% on total investment; but in fact 20 on the second hundred thalers or second 20 lb., in which he did not pay the objectified labour. Now assume that he is capable of making double that, say

lb.	*Thalers*	
80	400	Of this, take off 20 lb. for [necessary labour]
20 for necessary labour etc. =	100	
Leaves:	300	Of these, take off 4/5 for material
	240	etc.
Leaves:	60	A profit of 60 on 400 is = 6 on 40 = 15%.

In fact in the above example the capitalist's investment is only 180; on this he makes 20, or 11 1/9%.

The smaller the part of the outlay becomes which represents necessary labour, the greater the gain, although it stands in no obvious relation to the real surplus value, i.e. surplus labour. For example. In order for the capitalist to gain 10%, he has to spin 40 lb. of twist; the worker needs to spin only 20 = necessary labour. Surplus labour = necessary labour, 100% surplus value. This is our old law. But this is not the matter at issue here.

In the above example with the 40 lb., the *real value* of the pound is 5 thalers, and, like the capitalist, the worker himself, if he conducted his own business *as a worker* (and could advance himself enough funds to be able to realize the raw material etc. to the extent necessary to allow him to live as a worker), would sell the pound at 5 thalers. He would, however, produce only 20 lb., and from its sale he would use 4/5 to obtain new raw material, and 1/5 to live. The only thing he would make out of the 100 thalers would be his wages. The capitalist's gain comes not from selling the pound *too dear* – he sells it at its *exact value* – but from selling it above the *costs of production, his costs* (not *the* costs, for the 1/5 costs the worker surplus labour). If he sold at less than 5 thalers, he would be selling *below* the value, and the buyer would have the 1/5 of labour contained in every pound of twist above the investment etc., for nothing. But the capitalist calculates in this manner:

Value of 1 pound = 5 thalers
of 40 pounds = 200 thalers; from which take off costs:
180
20 Leaves 20.

What he calculates is not that he gains 20 thalers out of the second 100 thalers, but that he gains 20 on his entire investment of ... 180 thalers. This gives him a profit of 11 1/9%, instead of 20. He calculates further that, in order to make this profit, he has to sell 40 lb. 40 lb. at 5 thalers gives him not 1/5, or 20%, but 20 thalers distributed over 40 lb., or 1/2 a thaler per pound. At the price for which he sells the pound, he makes 1/2 a thaler out of 5 thalers; or 1 out of 10 thalers;

10% of the selling price. The price is determined by the price of the fractional unit (1 pound) multiplied by the number to be sold; here 1 pound at 5 thalers × 40. While this determination of price is correct for the capitalist's pocket, it is equally liable to lead one astray theoretically, in as much as it now seems as if an overcharge above the *real* value took place in each individual pound, and the origin of the surplus value in each individual pound has become invisible. This *determination of price by the multiplication of the value of the unit (measure) of the use value (pound, yard, ton etc.) with the number of these units produced* is important later in the theory of prices. There follows from it among other things that a decline in the price of the unit and an increase in the number of units – brought about by growth of the productive forces – shows that profit increases in relation with labour, or that the proportion [*Verhältnis*] of necessary labour declines in relation [*im Verhältnis*] to surplus labour – and not the opposite, as is the opinion of Mr Bastiat etc. [45] E.g. if labour grew, owing to productivity, to the point where the worker was producing twice as many pounds in the same time as before – presupposing that 1 lb. of twist renders him entirely the same service, regardless of its cost, and that twist, clothing, is all he needs to live – then the value added by labour to 20 lb. of twist would no longer amount to 1/5 but now only to 1/10, because he would be transforming the 20 lb. cotton into twist in 1/2 the time. To the 80 thalers which the raw material cost, there would then be added not 20 thalers but only 10. The 20 lb. would cost 90 thalers and each pound 90/20 or 4 10/20 thalers. But if the total labour time remained the same, then labour would now transform 80 lb. of cotton into twist, instead of 40. 80 lb. twist, the pound at 4 9/20 thalers, = 356 thalers. [46] The capitalist's account would be –

Total receipts	356	thalers;	deduct for labour
	90		
	266		Of which, take off for investment etc.
	239	17/89	
	26	72/89	
			The capitalist's gain thus 26 72/89 instead of 20. Say 27 (which a little too high (17/89 too high)). His total outlays etc. 330; over

12%, although he would make less on
the individual pound.

The capitalist’s gain from the value of the measure (unit) of use value – pound, yard, quarter etc. – decreases in proportion as the relation of living labour to raw material etc. – of newly added labour – decreases; i.e. the less labour time is necessary to give the raw material the form which the unit expresses. Yard of cloth etc. But on the other side, – since this identical with the increased productivity of labour, or the growth of surplus labour time – the number of these units grows, units in which surplus labour time is contained, i.e. labour time not paid for.

It further follows from the above that the price can fall *below* the value, and capital can still make a gain; he must sell, however, a number multiplied by the unit large enough to form a surplus over the number multiplied by the unit which forms the necessary price of labour. If the relation of labour to raw material etc. is 1/5, then he can sell at e.g. only 1/10 above the constant value, since the surplus labour *costs* him *nothing.* He then makes a present of 1/10 of the surplus labour to the consumer and realizes only 1/10 for himself. This very important in competition; overlooked in particular by Ricardo. The determination of prices is founded on the determination of values, but new elements enter in. The price, which originally appeared only as the value expressed in money, becomes further determined as itself a specific magnitude. If 5 thalers is the *value* of a pound of twist, i.e. the same labour time as is contained in 5 thalers is contained in 1 pound of twist, then this remains its value regardless of whether 4 or 4 million lb. of twist are being appraised. The moment of the NUMBER OF POUNDS, because it expresses the relation of surplus labour to necessary labour in another form, becomes decisively important in the *determination of price.* This matter brought to popular awareness in the question of the *ten hours’ bill* etc.

Specific accumulation *of capital (transformation of surplus labour (revenue) into capital). – Proudhon. Value- and price-determination. In antiquity (slaves) not overproduction but over-consumption*

It follows further from the above:

If the worker were to restrict himself to *necessary labour,* he would spin no more than 20 lb. of twist, and realize no more raw material, machinery etc. than would have a value of 80 thalers monthly. Apart from the raw material, machinery etc. which are required for the workers *reproduction,* self-maintenance, the capitalist must *necessarily* lay out capital in raw material (and machinery, even if not in the same proportion) for the objectification of surplus labour. (In agriculture, fishery, in short, the extractive industries, this is not absolutely necessary; it becomes so, however, when they are conducted on a large scale, i.e. *industrially;* it appears then as surplus outlay not in raw material itself, but in the instruments to take it out with.) These surplus outlays – i.e. the tendering of the material for surplus labour – of the objective elements of its realization [*Verwirklichung*] are actually what forms the specific so-called *provisional accumulation* of capital: the accumulation of the stock (let us say for the time being) *specifically* of capital. For it is stupid, as we shall see more closely, to regard it as a quality specific to capital – that the objective conditions of living labour must be present, as such – whether they are furnished by nature or produced in history. These *specific advances* which capital makes signify nothing more than that it *realizes* objectified surplus labour – surplus product – in new living surplus labour, instead of investing (spending) it, like, say, Egyptian kings or Etruscan priest-nobles for pyramids etc.

Into the *determination of prices* (as we shall also see with profit) there also enters – *fraud, reciprocal chicanery.* One party can win in exchange what the other loses; all they can distribute among themselves is the surplus value – capital as a class. But these proportions open a field for individual deception etc. (apart from supply and demand) which has nothing to do with the determination of value as such.

Thus, out the window goes Mr Proudhon’s discovery that the worker cannot buy back his product. The basis on which this rests is that he (Proudhon) understands nothing, either about value-determination or about price-determination. But, furthermore and regardless of that, his conclusion that *this is why* there is over production is false in this abstraction. In the slave relation, the masters are not troubled by the fact that the workers do not compete with them as consumers. (Nevertheless, *production for luxury* as it presents itself in antiquity is a necessary result of the slave relation. Not overproduction, but *over-consumption* and *insane consumption,* signifying, by its turn towards the monstrous and the bizarre, the downfall of the old system of states.)

After capital steps out of the production process as *product,* it must be transformed into money again. The money which previously appeared merely as realized commodity etc., now appears as *realized capital,* or, realized capital as *money.* This an aspect of *money* (as of capital). The mass of money as medium of circulation has nothing to do with the difficulty of making capital into a reality [*realisieren],* i.e. of realizing it [*verwerten].* This can already be seen from the above development.

The general rate of profit. – If the capitalist merely sells at* his own *cost of production, then it is a* transfer *to another capitalist. Worker gains almost nothing thereby

In the above example, where the capitalist, if he sells the pound of twist at 5 thalers – i.e. 40 lb. at 5 thalers each – hence sells the pound of twist at its *real value* and thereby gains 1/2 a thaler out of 5 (the selling price), 10% on the selling price, or 1/2 on 4 1/2, i.e. 11 1/9% of his outlay, if he sells at only 10% – assume now a profit of merely 9/20 of a thaler on 4 1/2 thalers (this is a 1/20 difference from 1/2 on 4 1/2 thalers; a difference of just 1 1/9%). He then sells the pound at 4 1/2 thalers + 9/20 of a thaler; i.e. at 4 19/20 thalers or the 40 lb. at 198 thalers. Now various cases are possible. The capitalist with whom he exchanges – to whom he sells his 40 lb. – assume him to be the owner of a silver mine, i.e. silver producer – pays him only 198 thalers – hence gives him 2 thalers too little objectified labour in silver for the labour objectified in 40 lb. of cotton. Posit that with this capitalist B, the proportions of the outlay are exactly the same, etc. If capitalist B also takes only 10 instead of 11 1/9, then for 200 thalers he could not demand 40 lb. twist, but only 39 3/5. It is therefore impossible that both capitalists at the same time sell at 1 1/9% too little, or that the one offered 40 lb. for 198 thalers and the other offered 200 thalers for 39 3/5 lb., a case that cannot occur. In the previously assumed case, capitalist B would have paid 1 1/9% too little in his purchase of 40 lb. twist, i.e. apart from the profit which he does not obtain from exchange, but which exchange merely confirms, i.e. a profit of 11 1/9, he would also have gained the 1 1/9% lost by the other capitalist, for a total of 12 2/9%. From his own workers – the labour set into motion by his own capital – he would have gained 11 1/9%; the additional 1 1/9% are surplus labour by the workers of capitalist A, which he appropriates for himself. The *general rate of profit* can therefore fall in one or another branch of business if competition etc. forces the capitalist to sell below the *value,* i.e. to realize a part of the surplus labour not for himself, but for those who buy from him. But the general rate cannot fall in this way; it can fall only if the proportion of surplus labour to necessary labour falls *relatively,* and this, as we saw earlier, takes place if the proportion is already very large, or, expressed differently, if the proportion of living labour set into motion by capital is very small – if the part of capital which exchanges for living labour is very small compared to that which exchanges for machinery and raw material. The general rate of profit can fall in that case, even though absolute surplus labour rises.

With that, we come to another point. A *general rate of profit* as such is possible only if the rate of profit in one branch of business is too high and in another too low; i.e. that a part of the surplus value – which corresponds to surplus labour – is transferred from one capitalist to the other. If in 5 branches of business, for example, the respective rate of profit is

A	**B**	**C**	**D**	**E**
15%,	12%,	10%,	8%,	5%

then the average rate is 10%; but, in order for this to exist in reality, capitalist A and B have to give up 7% to D and E – more particularly, 2 to D and 5 to E – while C remains as it was. It is impossible for rates of profit on the same capital of 100 to be equal, since the relations of surplus labour are altogether different, depending on the productivity of labour and on the relation between raw material, machinery and wages, and on the overall volume in which production takes place. But suppose that a given branch of business, E, is necessary, say, the bakery trade, then the average 10% has to be paid to it. But this can happen only if A and B credit E with a part of their surplus labour. The capitalist class thus to a certain extent distributes the total surplus value so that, to a certain degree, it [shares in it] evenly in accordance with the *size* of its capital, instead of in accordance with the surplus values actually created by the capitals in the various branches of business. The larger profit – arising from the real surplus labour within a branch of production, the really created surplus value – is pushed down to the average level by competition, and the deficit of surplus value in the other branch of business raised up to the average level by withdrawal of capitals from it, i.e. a favourable relation of demand and supply. Competition cannot lower this level itself, but merely has the tendency to create such a level. Further developments belong in the section on competition. This is realized [*realisiert*] by means of the relation of prices in the different branches of business, which fall *below* the *value* in some, rise *above* it in others. This makes it seem as if an equal sum of capital in unequal branches of business created *equal surplus labour or surplus value.*

Now in the above example, where capitalist A is forced, say by competition, to sell at a profit of 10% instead of 11 1/9%, and hence sells the pound of twist at 1/20 of a thaler too cheaply, the worker would continue to obtain 20 thalers as before, in money, his necessary wages; but in twist, he would obtain 4 4/90 lb. instead of 4 lb. If his wages were in twist, he would have obtained 4/20 of a thaler = 1/5 of a thaler or 6 silver groschen, i.e. 1% more than his necessary wages. If the worker works in a branch of business whose product lies entirely outside the sphere of his consumption, then he gains not a farthing in this operation; rather, for him it is a matter of performing a part of his surplus labour indirectly for capitalist B, instead of directly for capitalist A; i.e. through the mediation of capitalist A. He can gain from the fact that capitalist A lets go of a part of the labour objectified in his product for nothing, only if he is himself a consumer of this product, and only to the extent that he is such a consumer. Thus, if his consumption of twist makes up 1/10 of his expenditure, then he gains exactly 1/50 of a thaler from the operation (2/100 of a thaler out of 2 thalers, 1/100 of 1, exactly 1% of the 2 thalers), i.e. 1/10% of his total wages of 20 thalers, or, 7 1/5 pfennigs. This would be the proportion – 7 1/5 pfennigs – in which he would participate in his own surplus labour of 20 thalers. Such are the proportions of the surplus wages which the worker makes at best, when the *price* in the branch of business where he is occupied falls below the necessary value. In the *best case* – and this is impossible – the limit (in the instance given) is 6 silver groschen or 1%, i.e. if he could live exclusively on twist; i.e. in the best case his surplus wages are determined by the relation of necessary labour time to surplus labour time. In the luxury-goods industries proper, from whose consumption he is himself excluded, it is always = 0.

Now let us assume that capitalists A, B, C exchange among one another; the total product of each = 200 thalers. Let A produce twist, B grain and C silver; let the relations of surplus and necessary labour, and of outlays and profit be just the same. A sells 40 lb. twist at 198, instead of at 200 thalers, and loses 1 1/9% of his gains; ditto B his, say 40 bushels wheat, at 198 instead of 200; but C exchanges the labour objectified in his 200 thalers in full. Between A and B the relation is such that neither of them loses in the exchange with the other. A would obtain 40 bushels wheat, B 40 lb. twist; but each of them a value of only 198. C obtains 40 lb. twist or 40 bushels wheat for 198 thalers and in both cases pays 2 thalers too little, or obtains 2/3 lb. twist or 2/5 bushel wheat too much. But now assume that the relation takes the form that A sells his 40 lb. to the silver man, C, for 200 thalers, but C has to pay 202 to the grain man, B, or 2 thalers above its value. Between twist A and silver C everything is all right; both exchange at value with each other; but because B's price has risen above its value, the 40 lb. twist and the 200 thalers silver, when expressed in grain, have fallen by 1 1/9%, or, neither of them could in fact any longer buy 40 bushels grain for 200 thalers, but only 39 2/5. 39 2/5 bushels wheat would cost 200 thalers, or the single bushel wheat, [47] instead of 5 thalers, 5 1/20 thalers; 5 thalers 1 1/4 silver groschen. Now, in this last relation, assume that the worker's consumption consists 1/2 of wheat; his twist consumption was 1/10 of his income; his wheat consumption 5/10. On the 1/10 he had gained 1/10% on his total wages; on the wheat, he loses 5/10; thus on the whole he loses 4/10% instead of gaining. Although the capitalist would have paid him his necessary labour, his wages would fall beneath the necessary pay as a consequence of grain man B's overcharging. If this continued on, then his necessary *wages* would have to *rise.* Thus if the sale of twist by capitalist A is due to a rise above value in the price of *grain* or of other use values which form the most essential part of the worker's consumption – then capitalist A's worker would lose in the same relation as his consumption of the now more expensive product is greater than the cheaper product he himself produces. But if A had sold twist at 1 1/9% above its value, and B sold grain at 1 1/9% below, then, in the best case, if the worker consumed nothing but grain, he could gain at most 6 silver groschen, or, since we presupposed half in grain, only 3 silver groschen, or 3% on his wages of 20 thalers. Thus the worker may experience all three cases: his gain or loss from the operation = 0; it may depreciate his necessary wages, so that they no longer suffice, hence make him fall below the necessary minimum; it can thirdly bring him a surplus wage, which is resolved into a very small share of his own surplus labour.

We saw above that if the relation of necessary labour to the other conditions of production = 2/5 (20 out of 100 total outlay) or = 40% of the total value (in 20 lb. twist = 4 lb. twist) (or of 100 thalers, 80 raw material and instrument, 20 labour) and the relation of surplus labour to necessary labour is 100% (i.e. the same quantity), then the capitalist makes 11 1/9% on his outlay.

If he took only 10% and made a gift of the 1 1/9 or 2 thalers (transferred surplus value), then the worker, in so far as he is a consumer, would likewise gain, and in the best (impossible) case, if he lived only from the products of his master, it would [be], as we saw:

Suppose the capitalist sold the pound of twist at 4 15/20 (4 3/4) instead of at 5 thalers, then the worker would gain 5/20 on the pound, and 20/20 = 1 on 4 lb.; but 1 out of 20 = 1/20 = 5% (1 thaler out of 20); the capitalist would sell the 40 lb. at 4 15/20 thalers = 95/20 of a thaler × 40 = 190 thalers; his outlays 180, his gain = 10 = 5 6/9[%], his minus-gain = 5 6/9; if he, the capitalist, sold at 4 12/20, then the worker would gain 8/20 thalers per pound, 32/20 per 4 lb., 1 thaler 12/20 or 1 3/5 thalers on his total wages, i.e. 8 48/119%, while the capitalist would lose 16 thalers of the surplus gain, or would only keep altogether 184 thalers, or 4 thalers gain on 180 = 1/45 of 180 = 2 2/9%; would lose 8 8/9; assume finally the capitalist sold the pound of twist at 4 1/2 thalers; the 40 lb. at 180; his profit = 0; he would make the consumer a present of the worker's surplus value or surplus labour time, then the worker's gain = 1/2 of a thaler per lb., = 4/2 of a thaler = 2 thalers, or 2 thalers out of 20 = 10%.	1 1/9% loss on the capitalist's side:=	1% = 6 silver groschen on 20 thalers (= 1/5 of a thaler out of 20) gain above wages for the worker: = 1 thaler
	5 6/9; (= 10 thalers)	= 5% (1 thaler out of 20)
	= 8 8/9% (= 16)	= 8 48/119%

	(1 thaler 18 silver groschen)
Gain = 0 (loss = 11 1/9%)	
	= 10% (2 thalers) (*less than 1/2 pound*)

If on the other hand the capitalist had raised wages by 10% from 20 to 22 thalers, because, say, the demand for labour in his branch of business had risen above the supply – while he continued to sell the pound of twist at its value, i.e. at 5 thalers as before, then his profit would have fallen by only 2 thalers, from 200 to 198, i.e. by 1 1/9%, and would still have been 10%.

It follows from this that if the capitalist, say, out of consideration for Mr Proudhon, sold his commodities at the production costs they cost *him,* and if his total profit = 0, this would be merely a transfer of the surplus value or surplus labour time from capitalist A to B, C, D etc., and as regards his worker, his gain at best – i.e. his share of his own surplus labour – would be limited to that part of the wage which he consumed in the depreciated commodity; and if he spent his entire wages on it, the gain could not be greater than the proportion of necessary labour to the total product (in the above example 20: 200 = 1/10, 1/10 of 20 = 2 thalers). As regards the other workers, the case is entirely the same; they gain from the depreciated commodity only in relation (1) as they consume it; (2) relative to the size of their wage, which is determined by necessary labour. If the depreciated commodity were, e.g. grain – one of the staffs of life – then first its producer, the farmer, and following him all other capitalists, would make the discovery that the worker’s necessary wage is no longer the necessary wage; but stands above its level; hence it is brought down; hence ultimately only the surplus value of capitals A, B, C etc. is increased, and the surplus labour of those occupied in them.

Posit 5 capitalists, A, B, C, D and E. Let E produce a commodity which is consumed only by workers. E would then realize his profit purely in the exchange of his commodity with wages; but, as always, his profit would originate not in the exchange of his commodity for the workers’ money, but in the exchange of his capital with living labour. Posit that necessary labour relates in all 5 branches of business at 1/5; let 1/5 be surplus labour in all of them; let constant capital be = 3/5 in all. Capitalist E exchanges his product for 1/5 of capital A, 1/5 of capital B, 1/5 of capital C, 1/5 of capital D, and 1/5 constitutes his wages. He would make no profit on this last 1/5, as we have seen; or rather his profit would not arise from the fact that he gives the workers 1/5 of his capital in money, and that they buy back the same 1/5 from him as money – would not originate from the exchange with them as *consumers,* as centres of circulation. His whole transaction with them as consumers rests on the basis that he gives them his product in the form of money, and they give him back the same money for exactly the same fractional part of the product. With the workers of A, B, C, D, his relation is not that of capitalist to worker, but of C[ommodity] to M[oney], of vendor to buyer. We have presupposed that the workers of A, B, C, D consume no part of their own products; D does, however, exchange for 1/5 of the product of A, B, C and E, i.e. 4/5 of their product; but this exchange is only a detour to get to the wages which A, B, C and D pay their own workers. They each give the workers money to the value of 1/5 of their product, or 1/5 of their product as payment for necessary labour, and with this, with 4/5 of the value of their product or capital, they then buy E’s commodity. But this exchange with E is then only an indirect form of advancing the part of capital which represents necessary labour – i.e. *deduction* from their capital. They cannot therefore gain thereby. The gain comes from the realization of the remaining 4/5 of capital A, B, C, D, and this realization consists of each of them, through the exchange, getting back the labour objectified in his product, in another form. For each of them, since there is a division of labour, 3/5 replaces his constant capital, raw material and material of labour. Their gain – the realization of surplus labour time, its positing as surplus value – consists in the reciprocal realization of the last 1/5. It is not necessary that capitals A, B, C, D exchange the entire 4/5 with one another. Since they are, as capitalists, at the same time large consumers, and can in no way live on air, but since, as capitalists, they do not live from their labour either, they have nothing to exchange or to consume apart from other peoples’ products. That is, for their own consumption they exchange just that 1/5 which represents surplus labour time, the labour created by means of capital. Posit that each consumes 1/5 of this 1/5, i.e. 1/25, in the form of his own product. There remain 4/25 to be either realized or to be transformed into use values for their own consumption through exchange. Let A exchange 2/25 with B, 1/25 with C, 1/25 with E, and likewise on the part of B, C, E.

The case we have posited, where capital E realizes the whole of its profit in exchange with wages, is the most favourable – or expresses, rather, the only correct relation in which it is possible for capital to realize the surplus value created in *production* through *exchange* with the workers' consumption. But capitals A, B, C, D can realize their value in this case only through exchange among one another, i.e. through the exchange of capitalists among themselves. Capitalist E consumes nothing of his own commodity, since he has paid 1/5 of it to his own workers, exchanged 1/5 for 1/5 of capital A, 1/5 for 1/5 of capital B, 1/5 for 1/5 of capital C, 1/5 for 1/5 of capital D. A, B, C, D make no profit on this exchange, since it is the respective 1/5 which they have paid to their own workers.

Given the relation we have assumed, of 2/5 raw material, 1/5 machinery, 1/5 workers' necessaries, and 1/5 surplus product, from which Messrs the capitalists at the same time live and realize their surplus value, then we need, if the total product of each of A, B, C, D, E = 100, a producer E for workers' necessaries, 2 capitalists A and B, who produce raw materials for all the others, 1, C, who produces the machinery, and 1, D, who makes the surplus produce, The accounts would be these (the machinery-maker etc. has to produce every part of his commodity for himself):

		For labour	*Raw material*	*Machinery*	*Surplus product*		
(A)	Raw material manufacturer	20	40	20	20	= 100	2½
(B)	Ditto	20	40	20	20	= 100	2½
(C)	Machinery manufacturer	20	40	20	20	= 100	2½
(E)	Workers' necessaries	20	40	20	20	= 100	2½

(D)	Surplus producer	20	40	20	20	= 100
		10	20	10	10	= 50

E therefore exchanges his entire product of 100 for 20 in his own workers' wages, 20 in wages for workers of raw material A, 20 for the workers of raw material B, 20 for the workers of machinery maker C, 20 for the workers of surplus producer D; of this he exchanges 40 for raw material, 20 for machinery, 20 he obtains back for workers' necessaries, and 20 remain for him to buy surplus produce, from which he himself lives. Likewise the others in the relation. What constitutes their surplus value is the 1/5 or 20, which all of them can exchange for surplus product. If they consumed the entire surplus, then they would have come no further at the end than they were at the beginning, and the surplus value of their capital would not grow. Posit that they eat up only 10; or 1/10, half of the surplus value; then surplus producer D himself would eat up 10 less; and each of the others 10 less; all in all, then, he would sell only half of his commodity, = 50, and could not begin his business anew. Posit therefore that he consumes only 50 in consumables. Likewise, 50 in money, then each of the capitalists A, B, C, D, E, would accumulate 10 thalers in money. These would represent the surplus value not consumed. These 10 thalers, or together 50, could be realized, however, only by being laid out for new labour. In order to produce more raw material, A and B need 4 thalers more of living labour, and, since they have no additional machinery for it, more labour by hand to the amount of 6 thalers. Thus, out of the 400 thalers which exist in raw materials, machines and workers' necessaries, only 50 are there for capitalists' consumables. But each of the capitalists now owns a surplus of 10, out of which 4 are in raw material, 2 in machines, 2 in workers' necessaries, on which he must make a gain of 2 (like 100 from 80, as before); D has gained 10 on his 40 and can therefore increase his production in the same proportion, i.e. by 5. The next year he produces 7 1/2% more = 57 1/2.

This example may or may not be continued later. Does not actually belong here. This much is clear, that realization here takes place in the exchange among the capitalists, for although E produces only for workers' consumption, he exchanges with the others through the form of wages, 1/5 of A, 1/5 of B, 1/5 of C, 1/5 of D etc. A, B, C, D likewise exchange with E: not directly, but indirectly, in that each of them requires 1/5 from him as necessaries for his workers. The realization consists of each of them exchanging his own product for fractional parts of the products of the other four, and this in such a way that a part of the surplus product goes for the capitalist's own consumption, and a part is transformed into surplus capital with which to set new labour into motion. The realization consists of the *real possibility* of increased realization – production of new and larger values. It is clear here that D and E, where E represents all commodities consumed by the workers and D all those consumed by the capitalists, would have produced too much – that is, too much relative to the proportion of the part of capital going to the worker, or too much relative to the part of capital consumable by the capitalists (too much relative to the proportion by which they must increase their capital; and this proportion later obtains a minimum limit in the form of interest) – that *general overproduction* would take place, not because relatively *too little* [sic] had been produced of the commodities consumed by the workers or too little [sic] of those consumed by the capitalists, but because too much *of both* had been produced – *not* too much *for consumption,* but too much to retain *the correct relation between consumption and realization; too much for realization.*

Barrier of capitalist production. – Relation of surplus labour to necessary labour. Proportion of the surplus consumed by capital to that transformed into capital. – Devaluation during crises

In other words: At a given point in the development of the productive forces – for this will determine the relation of necessary labour to surplus labour – a fixed relation becomes established, in which the product is divided into one part – corresponding to raw material, machinery, necessary labour, surplus labour – and finally surplus labour divides into one part which goes to consumption and another which becomes capital again. This inner division, inherent in the concept of capital, appears in exchange in such a way that the exchange of the capitals among one another takes place in specific and restricted proportions – even if these are constantly changing, in the course of production. If the relations are e.g. those of 2/5 raw material, 1/5 machinery, 1/5 wages, 1/5 surplus product, of which 1/10 for consumption, 1/10 for new production – this is the division within capital – this will appear in the exchange process as distribution among, say, 5 capitals. This gives, in any case, both the sum total of the exchange which can take place, and the proportions in which each of these capitals must both exchange and produce. If the relation of necessary labour to the constant part of capital is, as e.g. in the above example, = 1/5:3/5, then we have seen that the capital which works for the consumption of capitalists and workers combined may not be greater than 1/5 + 1/10 of the 5 capitals, each of which represents 1, = 1 1/2 capitals. Given likewise is the relation in which each capital must exchange with each other one, which represents a specific one of its own moments. Finally, in which each of them must exchange at all. If, for example, the relation of raw material = 2/5, then the capitals which produce raw material can at any final point exchange no more than 3/5, while 2/5 must be regarded as fixed. (E.g. as seed etc. in agriculture.) *Exchange* in and for itself gives these conceptually opposite moments an indifferent being; they exist independently of one another; their inner necessity becomes *manifest* in the crisis, which puts a forcible end to their seeming indifference towards each other.

A revolution in the forces of production further alters these relations, *changes* these relations themselves, whose foundations – from the standpoint of capital and hence also of that of realization through exchange – always remains *the relation of necessary to surplus labour,* or, if you like, of the different moments of objectified to living labour. It is possible, as we have already indicated earlier, that the capital as well as the living labour capacity set free owing to the increase in productive forces must both lie dormant, because they are not present in the proportions in which production must take place on the basis of the newly developed productive forces. If it proceeds regardless of that, then ultimately a minus, a negative magnitude, will come out of the exchange on one side or the other.

The barrier always remains, that exchange – hence production as well – takes place in such a way that the relation of surplus labour to necessary labour remains the same – for this is = to the constancy [*Gleichbleiben*] of the realization of capital. The second relation – the proportion between the part of the surplus product consumed by capital and that part transformed anew into capital – is determined by the first relation. Firstly, *the magnitude of the sum to be divided into these two parts depends on this original relation;* secondly, just as the creation of surplus value by capital depends on the creation of surplus labour, so does the increase of capital as capital (accumulation, and, without accumulation, capital cannot form the foundation of production, since it would remain stagnant, and would not be an element of progress, required already by the mere increase of population etc.) depend on the transformation of a part of this surplus product into new capital. If the surplus value were simply consumed, then capital would *not* have realized itself as capital, and not produced itself as *capital,* i.e. as value which produces value.

We have seen that if 40 lb. of twist of a value of 200 thalers – because they contain labour time objectified in 200 thalers – are exchanged for 198 thalers, then not only does the manufacturer of twist lose 1 1/9% gain; but also his product is devalued, has been sold *below* its real value, although it is sold at a *price* which still leaves him a profit of 10%. On the other hand, the producer of silver gains 2 thalers. Keeps 2 thalers as liberated capital. Nevertheless, a devaluation has taken place as regards the total sum. For the sum is 398 thalers instead of 400. For, in the hand of the producer of silver, the 200 thalers of twist are also worth only 198; it is the same for him as if the productive force of his labour had increased to the point where the same objectified labour were contained in 200 thalers as before, but that 2 of these thalers had left the column of necessary outlays in his books and gone over into the column of surplus value, so that he would have paid 2 thalers less for necessary labour. The opposite could be the case only if the silver producer were able to re-sell for 200 thalers the 40 lb. of twist he bought at 198 thalers. Then he would have 202 thalers, and say he sold them to a manufacturer of silk who gave him silk to the value of 200 thalers in exchange for the 40 lb. of twist. The 40 lb. twist would then have been sold at their true value, although not first-hand by their producer, but rather second-hand, by their buyer, and the total accounts would look as follows: Exchanged, 3 products each containing objectified labour of a value of 200 thalers; hence *sum* of the values of the capitals: 600. The manufacturer of twist, A, the manufacturer of silver, B, the manufacturer of silk, C: A 198, B 202 (i.e. 2 extra from the first exchange and 200 in silk), C 200.

Total 600. In this case the combined value of the capitals remained the same, and all that took place was a displacement, in that B pocketed as an extra the value-fraction which A lost.

If A, the twist maker, could sell only 180 (the cost of the thing for *him*), and absolutely could not find a buyer for 20 twist, then objectified labour in the amount of 20 thalers would have become valueless. The same would be the case if he gave a value of 200 for 180 thalers; for B, the manufacturer of silver – to the extent that this necessity had arisen for A owing to overproduction of twist, so that B, too, could not get rid of the value contained in the 40 lb. twist for more than 180 – 20 thalers of his capital would have been set free. He would have in hand a relative surplus value of 20 thalers, but in absolute values – objectified labour time to the extent that it is exchangeable – he would have only 200 as before – that is, 40 lb. twist at 180 and 20 thalers liberated capital. It would be the same for him as if the production costs of twist had decreased, i.e. as if, owing to increased labour productivity, 40 lb. twist contained 20 thalers less labour time, or as if, with a working day = 4 thalers, 5 working days less were necessary in order to transform *x* lb. of cotton into 40 lb. twist; so that, then, he would have to exchange less labour time objectified in silver for the labour time objectified in twist. But the combined sum of the values on hand would be 380 instead of 400. Thus a *general depreciation* of 20 thalers would have taken place, or a destruction of capital to the amount of 20 thalers. A *general devaluation* thus takes place despite the fact that the *depreciation* of the twist manufacturer’s 40 lb. twist from 200 to 180 necessarily appears as an appreciation on the part of silver, a depreciation of twist relative to silver; and a general depreciation of prices as such always includes an appreciation of money, i.e. of the commodity in which all the others are appraised. Thus, in a crisis – a general depreciation of prices – there occurs up to a certain moment a *general devaluation* or *destruction of capital.* The devaluation, like the *depreciation,* can be absolute and not merely relative, because value expresses not merely a relation between one commodity and another, as does price, but rather the relation between the price of the commodity and the labour objectified in it, or between one amount of objectified labour of the same quality and another. If these amounts are not equal, then *devaluation* takes place, which is not outweighed by appreciation on the other side, for the other side expresses a fixed amount of objectified labour which remains unchanged by exchange. In general crises, this devaluation extends even to living labour capacity itself. In consequence of what has been indicated above, the destruction of value and capital which takes place in a crisis coincides with – or means the same thing as – a general growth of the *productive forces,* which, however, takes place not by means of a real increase of the productive force of labour (the extent to which this happens in consequence of crises is beside the point here), but by means of a decrease of the existing value of raw materials, machines, labour capacity. For example. The cotton manufacturer loses capital on his products (e.g. twist), but he buys the same value of cotton, labour etc. at a lower price. It is the same for him as if the *real value* of labour, of cotton etc., had decreased, i.e. as if they had been produced more cheaply owing to an increase in the productive force of labour. In the same way, on the other hand, a sudden general increase in the forces of production would relatively devalue all the *present values* which labour objectifies at the lower stage of the productive forces, and hence would destroy present capital as well as present labouring capacity. The other side of the crisis resolves itself into a real decrease in production, in living labour – in order to restore the correct relation between necessary and surplus labour, on which, in the last analysis, everything rests. (Thus it is by no means true, as Lord Overstone thinks – as a true usurer – that crises simply resolve themselves in enormous profits for the one, and tremendous losses for the other.) [48]

Capital coming out of the production process becomes money again

Exchange does not change the inner characteristics of realization; but it projects them to the outside; gives them a reciprocally independent form, and thereby lets their unity exist merely as an inner necessity, which must therefore come forcibly to the surface in crises. Both are therefore posited in the essence of capital: the devaluation [*Entwertung*] of capital in the production process, as well as the suspension of devaluation and the creation of the conditions for the realization [*Verwertung*] of capital. The process by which this takes place in reality can be examined only as soon as *real* capital, i.e. competition etc. –

the actual real conditions – have been examined. Does not belong here yet. On the other hand, *without* exchange the production of capital as such would not exist, since *realization* as such cannot exist without exchange. Without exchange, the only question of concern would be the measurement etc. of the *use value* produced, only use value as such.

After capital, in the production process, (1) has realized itself, i.e. created a new value; (2) become devalued, i.e. made the transition from money to the form of a particular commodity, it (3) realizes itself together with its new value, in that the product is thrown into circulation again, and, as C, is exchanged for M. At the point where we stand now, where capital is being examined only in general, the real difficulties of this third process are present only as *possibilities,* and are therefore suspended, again as *possibilities.* Therefore, the product now posited as having been transformed back into money.

Capital is thus now posited as money again, and money therefore posited in the *new* aspect of *realized capital,* not merely as realized price of the commodity. Or, the commodity realized in the price is now realized capital. We will examine this new aspect of money, or rather of capital as money, later. In accord with the initial nature of money, the only apparent feature by which capital – when transformed into money – may be measured is the new value which it has created; i.e. the first aspect of money as the general measure of commodities repeats itself; now as the measure of surplus value – of the realization of capital. In the form of money, this realization appears as measured by itself; as being its own measure. The capital was originally 100 thalers; because it is now 110, the measure of its realization is posited in its own form – as a proportion of the capital returned (returned to its money form) from the production process and from exchange, relative to the original capital; no longer as a relation between two unequal qualities – objectified and living labour – or necessary labour and surplus labour. When capital is posited as money, it is therefore posited in the first aspect of money, as measure of value. Here, however, this value is its own value, or the measure of its self, negation. [49] We will return to this (under profit).

The second form of money was that of the medium of circulation, and in this regard the money form of capital appeared as a mere vanishing moment for the purpose of exchanging it again, but not, as in the case of money as a medium of circulation in general, an exchange in return for commodities – use values – for final consumption, but rather an exchange in return for those particular use values in which it is able to begin its course as capital anew – raw material and instrument on the one hand, living labour capacity on the other. In this role it is *circulating capital,* about which later. However, the end-product of money in its role as medium of circulation is the beginning of the act of production with *posited* capital as the point of departure, and this is the point which we will here examine before we go further. (In the first aspect, *measure,* the *new value* did appear as measured; but the difference merely formal; instead of surplus labour, money – surplus labour objectified in a specific commodity. But the *qualitative* nature of this new value also undergoes a change – i.e. the magnitude of the measure itself, to be examined only later. Secondly, as medium of circulation the disappearance of the money form is also merely *formal.* It only becomes *essential* after not only the first but also the second circular path has been completed. Thus initially it results only in our standing again at the beginning of the *realization process.* We therefore begin to take up the continuation at *this point.*)

The third form of money, as independent value in a negative relation *vis-à-vis* circulation, is capital which does not step out of the production process into exchange again to become money. Rather, it is capital which becomes a commodity and enters into circulation in the form of self-sufficient value [*sich auf sich selbst beziehenden Werts*]. This third form presupposes capital in the earlier forms and at the same time forms the transition from *capital* to the *particular capitals,* the real capitals; since now, in this last form, capital already in its very concept divides into two capitals with an independent existence. Along with the duality, plurality in general is then given. Such is the march of this development. [50]

<Before we go any further, just one remark. *Capital in general,* as distinct from the particular capitals, does indeed appear (1) *only as an abstraction;* not an arbitrary abstraction, but an abstraction which grasps the specific characteristics which distinguish capital from all other forms of wealth – or modes in which (social) production develops. These are the aspects common to every capital as such, or which make every specific sum of values into capital. And the distinctions within this abstraction are likewise abstract particularities

which characterize every kind of capital, in that it is their position [*Position*] or negation [*Negation*] (e.g. fixed capital or circulating capital); (2) however, capital in general, as *distinct* from the particular real capitals, is itself a *real* existence. This is recognized by ordinary economics, even if it is not *understood,* and forms a very important moment of its doctrine of equilibrations etc. For example, capital in this *general form,* although belonging to individual capitalists, in its *elemental form* as capital, forms the capital which accumulates in the banks or is distributed through them, and, as Ricardo says, so admirably distributes itself in accordance with the needs of production. [51] Likewise, through loans etc., it forms a level between the different countries. If it is therefore e.g. a law of capital in general that, in order to realize itself, it must posit itself doubly, and must realize itself in this double form, then e.g. the capital of a particular nation which represents capital *par excellence* in antithesis to another will have to lend itself out to a third nation in order to be able to realize itself. This double positing, this relating to self as to an alien, becomes damn real in this case. While the general is therefore on the one hand only a mental [*gedachte*] mark of distinction [*differentia specifica],* it is at the same time a *particular* real form alongside the form of the particular and individual. [52] (We will return later to this point, which, while having more of a logical than an economic character, will nevertheless have a great importance in the course of our inquiry. The same also in algebra. For example, *a, b, c* are numbers as such; in general; but then again they are whole numbers as opposed to *a/b, b/c, c/b, c/a, b/a* etc., which latter, however, presuppose the former as their general elements.>

***Surplus labour or surplus value becomes surplus capital. All determinants of capitalist production now appear as results of (wage) labour itself. The realization process* [Verwirklichungsprozess] *of labour at the same time its de-realization process* [Entwirklichungsprozess]

The new value, then, [is] itself posited as capital again, as objectified labour entering into the process of exchange with living labour, and hence dividing itself into a constant part – the objective conditions of labour, material and instrument – and the conditions for the subjective condition of labour, the existence of living labour capacity, the necessaries, subsistence goods for the worker. With this second entrance by capital in this form, some points appear clarified which were altogether unclear in its first occurrence – as money in transition from its role as value to its role as capital. Now they are solved through the process of realization and production itself. In the first encounter, the *presuppositions* themselves appeared to come in from the outside, out of circulation; as external presuppositions for the arising of capital; hence not emergent from its inner essence, and not explained by it. These *external* presuppositions will now appear as moments of the motion of capital itself, so that it has itself – regardless how they may arise historically – pre-posited them as its own moments.

Within the production process itself, surplus value, the surplus value procured through compulsion by capital, appeared as *surplus labour,* itself in the form of living labour, which, however, since it cannot create something out of nothing, finds its objective conditions laid out before it. Now this *surplus labour* appears in objectified form as *surplus product,* and, in order to realize itself as capital, this surplus product divides into a double form: as *objective condition of labour* – material and instrument; as subjective – consumption goods for the living labour now to be put to work. The general form as value – objectified labour – and objectified labour coming out of circulation – is of course the general, self-evident presupposition. Further: the surplus product in its totality – which objectifies surplus labour in its totality – now appears as *surplus capital* (in contrast to the original capital, before it had undertaken this cycle), i.e. as independent exchange value, in which living labour capacity encounters its *specific use value.* All moments which confronted living labour capacity, and employed it as *alien, external* powers, and which consumed it under *certain conditions independent of itself,* are now posited as *its own product and result.*

Firstly: surplus value or the surplus product are nothing but a specific sum of objectified living labour – the sum of surplus labour. This new *value* which confronts living labour as independent, as engaged in exchange with it, as capital, is the *product of labour.* It is itself nothing other than the *excess of labour as such above necessary labour* – in objective form and hence as *value.*

Secondly: the particular forms which this value must adopt in order to realize itself anew, i.e. to posit itself as capital – on one side as raw material and instrument, on the other as subsistence goods for labour during the act of production – are likewise, therefore, only *particular* forms of surplus labour itself. Raw material and instrument are produced by it in such relations – or, it is itself objectively posited in production as raw material and instrument in such a proportion – that a given sum of necessary labour – i.e. living labour which reproduces (the value of) the consumption goods – can objectify itself in it, and objectify itself in it continuously, i.e. can always begin anew the diremption into the objective and subjective conditions of its self-preservation and self-reproduction. In addition to this, living labour, in the process of reproducing its objective conditions, has at the same time posited raw material and instrument in such proportions that it can realize itself in them as *surplus labour, as labour beyond the necessary,* and can hence make them into material for the creation of *new* values. The objective conditions of *surplus labour* – which are restricted to the proportion of raw material and instrument beyond the requirements of necessary labour, whereas the objective conditions of necessary labour divide within their objectivity into objective and subjective, into objective moments of labour as well as subjective (consumption goods for living labour) – therefore now appear, are therefore now posited, as the product, result, objective form, external existence of surplus labour itself. Originally, by contrast, the fact that instrument and necessaries were on hand in the amounts which made it possible for living labour to realize itself not only as *necessary,* but also as *surplus* labour – this appeared alien to living labour itself, appeared as an act of capital.

Thirdly: The independent, for-itself existence [*Fürsichsein*] of value *vis-à-vis* living labour capacity – hence its existence as capital – the objective, self-sufficient indifference, the *alien quality* [*Fremdheit*] of the objective conditions of labour *vis-à-vis* living labour capacity, which goes so far that these conditions confront the person of the worker in the person of the capitalist – as personification [53] with its own will and interest – this absolute *divorce, separation* of property, i.e. of the objective conditions of labour from living labour capacity – that they confront him as *alien property,* as the reality of other juridical persons, as the absolute realm of *their* will – and that labour therefore, on the other side, appears as *alien labour* opposed to the value personified in the capitalist, or the conditions of labour – this absolute separation between property and labour, between living labour capacity and the conditions of its realization, between objectified and living labour, between value and value-creating activity – hence also the alien quality of the content of labour for the worker himself – this divorce now likewise appears as a product of labour itself, as objectification of its own moments. For, in the new act of production itself – which merely confirmed the exchange between capital and living labour which preceded it – surplus labour, and hence the surplus product, the total product of labour in general (of surplus labour as well as necessary labour), has now been posited as capital, as independent and indifferent towards living labour capacity, or as exchange value which confronts its mere use value. Labour capacity has appropriated for itself only the subjective conditions of necessary labour – the means of subsistence for actively producing labour capacity, i.e. for its reproduction as mere labour capacity separated from the conditions of its realization – and it has posited these conditions themselves as *things, values,* which confront it in an alien, commanding personification. The worker emerges not only not richer, but emerges rather poorer from the process than he entered. For not only has he produced the conditions of necessary labour as conditions belonging to capital; but also the value-creating possibility, the realization [*Verwertung*] which lies as a possibility within him, now likewise exists as surplus value, surplus product, in a word as capital, as master over living labour capacity, as value endowed with its own might and will, confronting him in his abstract, objectless, purely subjective poverty. He has produced not only the alien wealth and his own poverty, but also the relation of this wealth as independent, self-sufficient wealth, relative to himself as the poverty which this wealth consumes, and from which wealth thereby draws new vital spirits into itself, and realizes itself anew. All this arose from the act of exchange, in which he exchanged his living labour capacity for an amount of objectified labour, except that this objectified labour – these external conditions of his being, and the independent externality [*Ausserihmsein*] (to him) of these objective conditions – now appear as posited by himself, as *his own product,* as his own self-objectification as well as the objectification of himself as a power independent of himself, which moreover rules over him, rules over him through his own actions.

In *surplus capital,* all moments are products of *alien labour – alien surplus labour* transformed into capital; means of subsistence for necessary labour; the objective conditions – material and instrument – whereby necessary labour can reproduce the value exchanged for it in means of subsistence; finally the amount of material and instrument required so that new surplus labour can realize itself in them, or a new surplus value can be created.

It no longer seems here, as it still did in the first examination of the production process, as if capital, for its part, brought with it any value whatever from circulation. Rather, the objective conditions of labour now appear as labour's product – both to the extent that they are value in general, and as use values for production. But while capital thus appears as the product of labour, so does the product of labour likewise appear as capital – no longer as a simple product, nor as an exchangeable commodity, but as *capital;* objectified labour as mastery, command over living labour. The product of labour appears as *alien property,* as a mode of existence confronting living labour as independent, as *value* in its being for itself; the product of labour, objectified labour, has been endowed by living labour with a soul of its own, and establishes itself opposite living labour as an *alien power:* both these situations are themselves the product of labour. Living labour therefore now appears from its own standpoint as acting within the production process in such a way that, as it realizes itself in the objective conditions, it simultaneously repulses this realization from itself as an alien reality, and hence posits itself as insubstantial, as mere penurious labour capacity in face of this reality alienated [*entfremdet*] from it, belonging not to it but to others; that it posits its own reality not as a being for it, but merely as a being for others, and hence also as mere other-being [*Anderssein*], or being of another opposite itself. [54] This realization process is at the same time the de-realization process of labour. It posits itself objectively, but it posits this, its objectivity, as its own not-being or as the being of its not-being – of capital. It returns back into itself as the mere possibility of value-creation or realization [*Verwertung*]; because the whole of real wealth, the world of real value and likewise the real conditions of its own realization [*Verwirklichung*] are posited opposite it as independent existences. As a consequence of the production process, the possibilities resting in living labour's own womb exist outside it as realities – but as *realities alien* to it, which form wealth in opposition to it.

In so far as the surplus product is realized anew as surplus capital, enters anew into the process of production and self-realization, it divides into (1) means of subsistence for the workers, to be exchanged for living labour capacity; let this part of *capital* be designated as *labour fund;* this labour fund, the part allotted for the maintenance of living labour capacity – and for its progressive maintenance, since surplus capital constantly grows – now likewise appears as the product of *alien* labour, labour alien to *capital,* as well as (2) its other component parts – the material conditions for the reproduction of a value = to these means of subsistence + a surplus value.

Further, if we consider this surplus capital, then the division of capital into a constant part – raw material and instrument with an antediluvian existence before labour – and a variable part, i.e. the necessary goods exchangeable for living labour capacity, appears as purely formal, in so far as both of them are equally *posited* by labour and are equally posited by it as its own *presuppositions*. Now, however, this internal division of capital appears in such a way that labour's own product – objectified surplus labour – splits into two component parts – the objective conditions for new realization of labour (1), and a labour fund for maintaining the possibility of this living labour, i.e. of living labour capacity as alive (2), but in such a way that labour capacity can only re-appropriate that part of its own result – of its own being in objective form – which is designated as labour fund, can appropriate and extract this part from the form of the alien wealth which confronts it, only by reproducing not merely its own value, but by also realizing that part of the new capital which represents the objective conditions for the realization of new surplus labour and surplus production, or production of surplus values. Labour has itself created a new fund for the employment of new necessary labour, or, what is the same, a fund for the maintenance of new living labour capacities, of workers, but has created at the same time the condition that this fund can be employed only if new surplus labour is employed on the extra part of the surplus capital. Thus, the production by labour of this surplus capital – surplus value – is at the same time the creation of the real necessity of new surplus labour, and thus surplus capital is itself at the same time the real possibility both of new surplus labour and of new surplus capital. It here becomes evident that labour itself progressively extends and gives an ever wider and fuller existence to the objective world of wealth as a power alien to labour, so that, relative to the values created or to the real conditions of value-creation, the penurious subjectivity of living labour capacity forms an ever more glaring contrast. The greater the extent to which labour objectifies itself, the greater becomes the objective world of values, which stands opposite it as alien – alien property. With the creation of surplus capital, labour places itself under the compulsion to create yet further surplus capital etc. etc.

In regard to the original not-surplus capital, the relation has changed, as regards labour capacity, in so far as (1) the part of it which is exchanged for necessary labour has been reproduced by this labour itself, i.e. no longer comes to it out of circulation, but is its own product; and (2) that part of the value which, as raw material and instrument, represents the real conditions for the realization [*Verwertung*] of living labour, has been maintained by it itself in the production process; and, since every use value by its nature consists of transitory material, but since exchange value is present, exists, only in use value, therefore this maintenance = protection from decay and ruin, or negation of the transitory nature of the values owned by the capitalists; hence, this maintenance means to posit them as values for-themselves, as *indestructible wealth.* Hence, this original sum of values has been posited for the first time as capital in the production process, by living labour.

Formation of surplus capital I. – Surplus capital II. – Inversion of

the law of appropriation. – Chief result of the production and realization process: the reproduction and new production of the relation of capital and labour itself, of capitalist and worker

Now, from the standpoint of capital: As regards the *surplus capital,* the capitalist represents value for-itself, money in its third moment, wealth, by means of simple *appropriation of alien labour;* since every moment of surplus capital, material, instrument, necessaries, resolves into *alien labour,* which the capitalist does not appropriate by means of *exchange* for existing values, but has appropriated *without exchange.* True, the exchange of a part of *values belonging to him,* or of *objectified labour* possessed by him, for alien living labour capacity, appears as the *original precondition* for this *surplus capital.* For the formation of *surplus capital I,* if we give that name to the surplus capital emerging from the original production process, i.e. for the *appropriation of alien labour,* of *objectified alien labour,* it appears as a condition that the capitalist should possess *values,* of which he *formally* exchanges one part for living labour capacity. We say formally, because living labour must replace and return to him these *exchanged* values as well. But be this as it may. In any case, it appears as a condition for the formation of surplus capital I, i.e. for the appropriation of alien labour or of the values in which it is objectified, that there must be an exchange of values belonging to the capitalist, thrown into circulation by him, and supplied to living labour capacity by him – of values which do *not* arise from his *exchange* with living labour, or not from his relation as *capital* to *labour.*

But now let us think of this surplus capital as having been thrown back into the production process, as realizing its surplus value anew in exchange, and as appearing anew as new surplus capital at the beginning of a third production process. This, *surplus capital II,* has different presuppositions from surplus capital I. The presupposition of surplus capital I was the existence of values belonging to the capitalist and thrown by him into circulation, or, more exactly, into the exchange with living labour capacity. The presupposition of surplus capital II is nothing more than the existence of surplus capital I; i.e. in other words, the presupposition that the capitalist has already appropriated alien labour without exchange. This puts him into a position where he is able to begin the process again and again. True, in order to create surplus capital II, he had to exchange a part of the value of surplus capital I in the form of means of subsistence for living labour capacity, but the values he gave in that exchange were not values which he originally put into circulation out of his own funds; they were, rather, objectified alien labour which he appropriated without giving any equivalent whatever, and which he now re-exchanges for alien living labour; in the same way, moreover, as the material etc. in which this new labour realizes itself and in which it creates surplus value have come into his hands without exchange, by mere appropriation. *The previous appropriation of alien labour now appears as the simple precondition for the new appropriation of alien labour;* or, his ownership of alien labour in objective (material) form, in the form of existing values, appears as the condition of his ability to appropriate new alien *living* labour capacity, hence surplus labour, labour without equivalent. The fact that he has previously confronted living labour as capital appears as the only condition required in order that he may not only maintain himself as capital, but also, as a growing capital, increasingly *appropriate* alien labour without equivalent; or, that he may extend his power, his existence as capital opposite living labour capacity, and on the other side constantly posit living labour capacity anew in its subjective, insubstantial penury as living labour capacity. Property – previous, or objectified, alien labour – appears as the only condition for further appropriation of present or living alien labour. In so far as surplus capital I was created by means of a simple exchange between objectified labour and living labour capacity – an exchange entirely based on the laws of the exchange of equivalents as measured by the quantity of labour or labour time contained in them – and *in so far as* the legal expression of this exchange presupposed nothing other than everyone’s right of property over his own products, and of free disposition over them – but in so far as the relation of surplus capital II to I is therefore a consequence of this first relation – we see that, by a peculiar logic, the right of property undergoes a dialectical inversion [*dialektischer Umschlag*], so that on the side of capital it becomes the right to an alien product, or the right of property over alien labour, the right to appropriate alien labour without an equivalent, and, on the side of labour capacity, it becomes the duty to relate to one’s own labour or to one’s own product as to *alien property.* The right of property is inverted, to become, on the one side, the right to appropriate alien labour, and, on the other, the duty of respecting the product of one's own labour, and one's own labour itself, as values belonging to others. The exchange of equivalents, however, which appeared as the original operation, an operation to which the right of property gave legal expression, has become turned round in such a way that the exchange by one side is now only illusory, since the part of capital which is exchanged for living labour capacity, firstly, is itself *alien labour,* appropriated without equivalent, and, secondly, *has to be replaced with a surplus by living labour capacity,* is thus in fact not consigned away, but merely changed from one form into another. The relation of exchange has thus dropped away entirely, or is a *mere semblance.* Furthermore, the right of property originally appeared to be based on one's own labour. Property now appears as the right to alien labour, and as the impossibility of labour appropriating its own product. The complete separation between property, and, even more so, wealth, and labour, now appears as a consequence of the law which began with their identity.

Finally, the result of the process of production and realization is, above all, the reproduction and new production of the *relation of capital and labour itself,* of *capitalist and worker.* This social relation, production relation, appears in fact as an even more important result of the process than its material results. And more particularly, within this process the worker produces himself as labour capacity, as well as the capital confronting him, while at the same time the capitalist produces himself as capital as well as the living labour capacity confronting him. Each reproduces itself, by reproducing its other, its negation. The capitalist produces labour as alien; labour produces the product as alien. The capitalist produces the worker, and the worker the capitalist etc.

Original accumulation of capital. *(The real accumulation). – Once developed historically, capital itself creates the conditions of its existence (not as conditions for its arising, but as results of its being). – (Performance of personal services, as opposed to wage labour.) – Inversion of the law of appropriation. Real alien relation* [Fremdheit] *of the worker to his product. Division of labour. Machinery etc.*

Once production founded on capital is presupposed – money has become transformed into capital actually only at the *end of the first production* process, which resulted in its reproduction and in the new production of surplus capital I; surplus capital I, however, is itself *posited,* realized as surplus capital, only when it has produced surplus capital II, i.e. as soon as those presuppositions of money, while it is in the process of passing over into capital, which still lie outside the movement of *real* capital have vanished, and when capital has therefore itself posited, and posited in accordance with its immanent essence, the conditions which form its point of departure in production – [then] the condition that the capitalist, in order to posit himself as capital, must bring values into circulation which he created with his own labour – or by some other means, excepting only already available, previous wage labour – belongs among the antediluvian conditions of capital, belongs to its *historic presuppositions,* which, precisely as such *historic* presuppositions, are past and gone, and hence belong to the *history of its formation,* but in no way to its *contemporary* history, i.e. not to the real system of the mode of production ruled by it. While e.g. the flight of serfs to the cities is one of the *historic* conditions and presuppositions of urbanism, it is not a *condition,* not a moment of the reality of developed cities, but belongs rather to their *past* presuppositions, to the presuppositions of their becoming which are suspended in their being. The conditions and presuppositions of the *becoming,* of the *arising,* of capital presuppose precisely that it is not yet in being but merely in *becoming;* they therefore disappear as real capital arises, capital which itself, on the basis of its own reality, posits the conditions for its realization. Thus e.g. while the process in which money or value for-itself originally becomes capital presupposes on the part of the capitalist an accumulation – perhaps by means of savings garnered from products and values created by his own labour etc., which he has undertaken as a *not-capitalist,* i.e. while the presuppositions under which money becomes capital appear as given, external *presuppositions* for the arising of capital – [nevertheless,] as soon as capital has become capital as such, it creates its own presuppositions, i.e. the possession of the real conditions of the creation of new values *without exchange* – by means of its own production process. These presuppositions, which originally appeared as conditions of its becoming – and hence could not spring from its *action as capital* – now appear as results of its own realization, reality, as *posited by it – not as conditions of its arising, but as results of its presence.* It no longer proceeds from presuppositions in order to become, but rather it is itself presupposed, and proceeds from itself to create the conditions of its maintenance and growth. Therefore, the conditions which preceded the creation of surplus capital I, or which express the becoming of capital, do not fall into the sphere of that mode of production for which capital serves as the presupposition; as the historic preludes of its becoming, they lie behind it, just as the processes by means of which the earth made the transition from a liquid sea of fire and vapour to its present form now lie beyond its life as finished earth. That is, individual capitals can continue to arise e.g. by means of hoarding. But the hoard is transformed into capital only by means of the exploitation of labour. The bourgeois economists who regard capital as an eternal and *natural* (not historical) form of production then attempt at the same time to legitimize it again by formulating the conditions of its becoming as the conditions of its contemporary realization; i.e. presenting the moments in which the capitalist still appropriates as not-capitalist – because he is still becoming – as the very conditions in which he appropriates *as capitalist.* These attempts at apologetics demonstrate a guilty conscience, as well as the inability to bring the mode of appropriation of capital as capital into harmony with the *general laws of property* proclaimed by capitalist society itself. On the other side, much more important for us is that our method indicates the points where historical investigation must enter in, or where bourgeois economy as a merely historical form of the production process points beyond itself to earlier historical modes of production. In order to develop the laws of bourgeois economy, therefore, it is not necessary to write the *real history of the relations of production*. But the correct observation and deduction of these laws, as having themselves become [55] in history, always leads to primary equations – like the empirical numbers e.g. in natural science – which point towards a past lying behind this system. These indications [*Andeutung*], together with a correct grasp of the present, then also offer the key to the understanding of the past – a work in its own right which, it is to be hoped, we shall be able to undertake as well. [56] This correct view likewise leads at the same time to the points at which the suspension of the present form of production relations gives signs of its becoming – foreshadowings of the future. Just as, on one side the pre-bourgeois phases appear as *merely historical,* i.e. suspended presuppositions, so do the contemporary conditions of production likewise appear as engaged in *suspending themselves* and hence in positing the *historic presuppositions* for a new state of society.

Now, if we initially examine the relation such as it has become, value having become capital, and living labour confronting it as mere use value, so that living labour appears as a mere means to realize objectified, dead labour, to penetrate it with an animating soul while losing its own soul to it – and having produced, as the end-product, alien wealth on one side and [, on the other,] the penury which is living labour capacity's sole possession – then the matter is simply this, that the process itself, in and by itself, posits the real objective conditions of living labour (namely, material in which to realize itself, instrument with which to realize itself, and necessaries with which to stoke the flame of living labour capacity, to protect it from being extinguished, to supply its vital processes with the necessary fuels) and posits them as alien, independent existences – or as the mode of existence of an *alien person,* as self-sufficient values for-themselves, and hence as values which form wealth alien to an isolated and subjective labour capacity, wealth of and for the capitalist. The objective conditions of living labour appear as *separated, independent* [*verselbständigte*] values opposite living labour capacity as subjective being, which therefore appears to them only as a value of *another kind* (not as value, but different from them, as use value). Once this separation is given, the production process can only produce it anew, reproduce it, and reproduce it on an expanded scale. How it does this, we have seen. The objective conditions of living labour capacity are presupposed as having an existence independent of it, as the objectivity of a subject distinct from living labour capacity and standing independently over against it; the reproduction and *realization* [*Verwertung*], i.e. the expansion of these *objective conditions,* is therefore at the same time their own reproduction and new production as the wealth of an alien subject indifferently and independently standing over against labour capacity. What is reproduced and produced anew [*neuproduziert*] is not only the *presence* of these objective conditions of living labour, *but also their presence as independent values, i.e. values belonging to an alien subject,* *confronting this living labour capacity.* The objective conditions of labour attain a subjective existence *vis-à-vis* living labour capacity – capital turns into capitalist; on the other side, the merely subjective presence of the labour capacity confronted by its own conditions gives it a merely indifferent, objective form as against them – it is merely a *value* of a particular use value *alongside* the conditions of its own realization [*Verwertung*] as *values* of another use value. Instead of their being realized [*realisiert*] in the production process as the conditions of its realization [*Verwirklichung*], what happens is quite the opposite: it comes out of the process as mere condition for *their* realization [*Verwertung*] and preservation as values for-themselves opposite living labour capacity. The material on which it works is *alien* material; the instrument is likewise an *alien* instrument; its labour appears as a mere accessory to their substance and hence objectifies itself in things not *belonging to it.* Indeed, living labour itself appears as *alien vis-à-vis* living labour capacity, whose labour it is, whose own life's expression [*Lebensäusserung*] it is, for it has been surrendered to capital in exchange for objectified labour, for the product of labour itself. Labour capacity relates to its labour as to an alien, and if capital were willing to pay it *without* making it labour it would enter the bargain with pleasure. Thus labour capacity's own labour is as alien to it – and it really is, as regards its direction etc. – as are material and instrument. Which is why the product then appears to it as a combination of alien material, alien instrument and alien labour – as *alien property,* and why, after production, it has become poorer by the life forces expended, but otherwise begins the drudgery anew, existing as a mere subjective labour capacity separated from the conditions of its life. The recognition [*Erkennung*] of the products as its own, and the judgement that its separation from the conditions of its realization is improper – forcibly imposed – is an enormous [advance in] awareness [*Bewusstsein*], itself the product of the mode of production resting on capital, and as much the knell to its doom as, with the slave's awareness that he *cannot be the property of another,* with his consciousness of himself as a person, the existence of slavery becomes a merely artificial, vegetative existence, and ceases to be able to prevail as the basis of production.

However, if we consider the original relation, before the entry of money into the self-realization process, then various conditions appear which have to have arisen, or been given historically, for money to become capital and labour to become capital-positing, capital-creating labour, wage labour. *(Wage labour,* here, in the strict economic sense in which we use it here, and no other – and we will later have to distinguish it from other forms of labour for day-wages etc. – is capital-positing, capital-producing labour, i.e. living labour which produces both the objective conditions of its realization as an activity, as well as the objective moments of its being as labour *capacity,* and produces them as alien powers opposite itself, as *values for-themselves, independent of it.)* The essential conditions are themselves posited in the relation as it appears originally: (1) on the one side the presence of living labour capacity as a merely *subjective* existence, separated from the *conditions* of living labour as well as from the *means of existence, the necessary goods,* the means of self-preservation of living *labour capacity;* the living possibility of labour, on the one side, in this complete abstraction; (2) the value, or objectified labour, found on the other side, must be an accumulation of use values sufficiently large to furnish the objective conditions not only for the production of the products or values required to reproduce or maintain living labour capacity, but also for the absorption of surplus labour – to supply the objective material for the latter; (3) a free exchange relation – money circulation – between both sides; between the extremes a relation founded on exchange values – not on the master–servant relation – i.e., hence, production which does not directly furnish the producer with his necessaries, but which is mediated through exchange, and which cannot therefore usurp alien labour directly, but must buy it, exchange it, from the worker himself; finally (4) one side – the side representing the objective conditions of labour in the form of independent values for-themselves – must present itself as *value,* and must regard the positing of value, self-realization, money-making, as the ultimate purpose – not direct consumption or the creation of use value.

So long as *both* sides exchange their labour with one another in the form of *objectified* labour, the relation is impossible; it is likewise impossible if *living labour capacity* itself appears as the property of the other side, hence as not engaged in exchange. (The fact that slavery is possible at individual points within the bourgeois system of production does not contradict this. However, slavery is then possible there only because it does not exist at other points; and appears as an anomaly opposite the bourgeois system itself.)

The conditions under which the relation appears at the origin, or which appear as the historic presuppositions of its becoming, reveal at first glance a two-sided character – on one side, dissolution of lower forms of living labour; on the other, dissolution of happier forms of the same.

The first presupposition, to begin with, is that the relation of slavery or serfdom has been suspended. Living labour capacity belongs to itself, and has disposition over the expenditure of its forces, through exchange. Both sides confront each other as persons. *Formally,* their relation has the equality and freedom of exchange as such. As far as concerns the legal relation, the fact that this form is a mere *semblance,* and a *deceptive semblance,* appears as an *external* matter. What the free worker sells is always nothing more than a specific, particular measure of force-expenditure [*Kraftäusserung*]; labour capacity as a totality is greater than every particular expenditure. He sells the particular expenditure of force to a particular capitalist, whom he confronts as an independent *individual.* It is clear that this is not his relation to the existence of capital as capital, i.e. to the capitalist class. Nevertheless, in this way everything touching on the individual, real person leaves him a wide field of choice, of arbitrary will, and hence of formal freedom. In the slave relation, he belongs to the *individual, particular* owner, and is his labouring machine. As a totality of force-expenditure, as labour capacity, he is a thing [*Sache*] belonging to another, and hence does not relate as subject to his particular expenditure of force, nor to the act of living labour. In the serf relation he appears as a moment of property in land itself, is an appendage of the soil, exactly like draught-cattle. In the slave relation the worker is nothing but a living labour-machine, which therefore has a value for others, or rather is a value. The totality of the free worker's labour capacity appears to him as his property, as one of his moments, over which he, as subject, exercises domination, and which he maintains by expending it. This to he developed later under wage labour.

The exchange of objectified labour for living labour does not yet constitute either capital on one side or wage labour on the other. The entire class of so-called *services* from the bootblack up to the king falls into this category. Likewise the free day-labourer, whom we encounter sporadically in all places where either the oriental community [*Gemeinwesen*] or the western commune [*Gemeinde*] consisting of free landowners dissolves into individual elements – as a consequence of increase of population, release of prisoners of war, accidents by which the individual is impoverished and loses the objective conditions of his self-sustaining labour, owing to division of labour etc. If A exchanges a value or money, i.e. objectified labour, in order to obtain a service from B, i.e. living labour, then this can belong:

(1) *within the relation of simple circulation.* Both in fact exchange only use values with one another; one exchanges necessaries, the other labour, a service which the other wants to consume, either directly – personal service – or he furnishes him the material etc. from which, with his labour, with the objectification of his labour, he makes a use value, a use value designed for A's consumption. For example, when the peasant takes a wandering tailor, of the kind that existed in times past, into his house, and gives him the material to make clothes with. Or if I give money to a doctor to patch up my health. What is important in these cases is the service which both do for one another. *Do ut facias* here appears on quite the same level as *facio ut des,* or *do ut des.* [57] The man who takes the cloth I supplied to him and makes me an article of clothing out of it gives me a use value. But instead of giving it directly in objective form, he gives it in the form of activity. I give him a completed use value; he completes another for me. The difference between previous, objectified labour and living, present labour here appears as a merely formal difference between the different tenses of labour, at one time in the perfect and at another in the present. It appears in fact as a merely formal difference, a difference mediated by division of labour and by exchange, whether B himself produces the necessaries on which he has to subsist, or whether he obtains them from A and, instead of producing the necessaries himself, produces an article of clothing, in exchange for which he obtains them from A. In both cases he can take possession of the use value possessed by A only by giving him an equivalent for it; which, in the last analysis, always resolves itself into his own living labour, regardless of the objective form it may adopt, whether before the exchange is concluded, or as a consequence of it. Now, the article of clothing not only contains a specific, form-giving labour – a specific form of usefulness imparted to the cloth by the movement of labour – but it contains also a certain

quantity of labour – hence not only use value, but *value* generally, *value* as such. But this value does not exist for A, since he consumes the article, and is not a clothes-dealer. He has therefore bought the labour not as *value-positing* labour, but as an activity which creates utility, use value. In the case of personal services, this use value is consumed as such without making the transition from the form of movement [*Bewegung*] into the form of the object [*Sache*]. If, as is frequently the case in simple relations, the performer of the service does not obtain *money,* but direct use values themselves, then it no longer even seems as if *value* were being dealt in on one or the other side; merely use values. But even given that A pays money for the service, this is not a transformation of his money into capital, but rather the positing of his money as mere medium of circulation, in order to obtain an object for consumption, a specific use value. This act is for that reason not an act which produces wealth, but the opposite, one which consumes wealth. The point for A is not the objectification in the cloth of labour as such, of a certain amount of labour time, hence *value,* but rather the satisfaction of a certain need. Here A sees his money not *realized* but *devalued* in its transposition from the form of value into that of use value. Labour is here exchanged not as use value for value, but as itself a particular use value, as value for use. The more frequently A repeats the exchange, the poorer does he become. This exchange is not an *act of wealth-getting* for him, not an act of *value creation,* but of *devaluation* of the values he has in hand, in his possession. The money which A here exchanges for living labour – service in kind, or service objectified in a thing – is not *capital* but revenue, money as a medium of circulation in order to obtain use value, money in which the form of value is posited as merely vanishing, not money which will preserve and realize itself as such through the acquisition of labour. Exchange of *money as revenue,* as a mere medium of circulation, for living labour, can never posit money as capital, nor, therefore, labour as wage labour in the economic sense. A lengthy disquisition is not required to show that to consume (spend) money is not the same as to produce money. In situations in which the greatest part of surplus labour appears as agricultural labour, and where the owner of the land therefore appears as owner both of surplus labour and of the surplus product, it is the revenue of the owner of the land which forms the labour fund for the free worker, for the worker in manufactures (here, hand crafts) as opposed to the agricultural labourers. The exchange with them [58] is a form of the consumption of the owner of the land – he divides another part of his revenue directly – for personal services, often only the illusion of services, with a heap of retainers. In Asiatic societies, where the monarch appears as the exclusive proprietor of the agricultural surplus product, whole cities arise, which are at bottom nothing more than wandering encampments, from the exchange of his revenue with the 'free hands', as Steuart calls them. [59] There is nothing of wage labour in this relation, but it *can* stand in opposition to slavery and serfdom, though *need* not do so, for it always repeats itself under various forms of the overall organization of labour. To the extent that *money* mediates this exchange the determination of prices will become important on both sides, but it will do so for A only in so far as he does not want to pay too much for the *use value* of the labour; not in so far as he is concerned with its *value.* The essence of the relation remains unchanged even if this price, which begins as conventional and traditional, is thereafter increasingly determined economically, first by the relation of demand and supply, finally by the production costs at which the vendors themselves of these living services can be produced; nothing is essentially changed thereby, because the determination of prices remains a merely formal moment for the exchange of mere use values, as before. This determination itself, however, is created by other relations, by the general laws and the self-determination of the ruling mode of production, acting, as it were, behind the back of this particular act of exchange. One of the forms in which this kind of pay [*Besoldung*] first appears in the old communities is where an *army* is maintained. The pay [*Sold*] of the common soldier is also reduced to a minimum – determined purely by the production costs necessary to procure him. But he exchanges the performance of his services not for *capital,* but for the revenue of the state.

In bourgeois society itself, all exchange of personal services for revenue – including labour for personal consumption, cooking, sewing etc., garden work etc., up to and including all of the unproductive classes, civil servants, physicians, lawyers, scholars etc. – belongs under this rubric, within this category. All menial servants etc. By means of their services – often coerced – all these workers, from the least to the highest, obtain for themselves a share of the surplus product, of the capitalist's *revenue.* But it does not occur to anyone to think that by means of the exchange of his revenue for such services, i.e. through private consumption, the capitalist posits himself as capitalist. Rather, he thereby spends the fruits of his capital. It does not change the nature of the relation that the proportions in which revenue is exchanged for this kind of living labour are themselves determined by the general laws of production.

As we have already mentioned in the section on *money,* [60] it is here rather the performer of the service who actually posits *value;* who transposes a use value – a certain kind of labour, service etc. – into *value, money.* Hence in the Middle Ages, those who are oriented towards the production and accumulation of money proceed partly not from the side of the consuming landed nobility, but quite the opposite, from the side of living labour; they accumulate and thus become capitalists, δυνάμει, for a later period. The emancipated serf becomes, in part, the capitalist.

It thus does not depend on the general relation, but rather on the natural, particular quality of the service performed, whether the recipient of payment receives it as day-wages, or as an honorarium, or as a sinecure – and whether he appears as superior or inferior in rank to the person paying for the service. However, with the presupposition of capital as the dominant power, all these relations become more or less *dishonoured.* But this does not belong here yet – this *demystification* [*Entgötterung*] of personal services, regardless of the lofty character with which tradition may have poetically endowed them.

It is not, then, simply the exchange of *objectified labour* for *living* labour – which appear, from this standpoint, as two different aspects, as use values in different forms, the one objective, the other subjective – which constitutes capital and hence wage labour, but rather, the exchange of objectified labour as *value,* as self-sufficient value, for living labour as *its* use value, a use value not for a specific, particular use or consumption, but as use value for *value.*

In the exchange of money for labour or service, with the aim of direct consumption, a real exchange always takes place; the fact that *amounts of labour* are exchanged on both sides is of merely *formal* interest for measuring the *particular* forms of the utility of labour by comparing them with each other. This concerns only the *form* of the exchange; but does not form its *content.* In the exchange of capital for labour, *value* is not a measure of the exchange of two use values, but is rather the *content of the exchange* itself.

(2) In periods of the dissolution of *pre-bourgeois* relations, there sporadically occur free workers whose services are bought for purposes not of consumption, but of *production;* but, *firstly,* even if on a large scale, for the production only of *direct* use values, not of *values;* and *secondly,* if a nobleman e.g. brings the free worker together with his serfs, even if he re-sells a part of the worker's product, and the free worker thus creates *value* for him, then this exchange takes place only for the superfluous [product] and only for the sake of superfluity, for *luxury consumption;* is thus at bottom only a veiled purchase of alien labour for immediate consumption or as use value. Incidentally, wherever these free workers increase in number, and where this relation grows, there the old mode of production – commune, patriarchal, feudal etc. – is in the process of dissolution, and the elements of real wage labour are in preparation. But these free servants [*Knechte*] can also emerge, as e.g. in Poland etc., and vanish again, without a change in the mode of production taking place.

<In order to express the relations into which capital and wage labour enter as *property relations* or *laws,* we need do no more than express the conduct of both sides in the *realization process* as an *appropriation process.* For example, the fact that surplus labour is posited as surplus value of capital means that the worker does not appropriate the product of his own labour; that it appears to him as *alien property;* inversely, that *alien labour* appears as the property of capital. This second law of bourgeois property, the inversion of the first – which, through laws of inheritance etc., attains an existence independent of the accidental transitoriness of individual capitalists – becomes just as established in law as the first. The first is the identity of labour with property; the second, labour as negated property, or property as negation of the alien quality of alien labour. In fact, in the production process of capital, as will be seen more closely in its further development, labour is a totality – a combination of labours – whose individual component parts are alien to one another, so that the overall process as a totality is *not* the *work* of the individual worker, and is furthermore the work of the different workers together only to the extent that they are [forcibly] combined, and do not [voluntarily] enter into combination with one another. The combination of this labour appears just as subservient to and led by an alien will and an alien intelligence –

having its *animating unity* elsewhere – as its material unity appears subordinate to the *objective unity* of the *machinery,* of fixed capital, which, as *animated monster,* objectifies the scientific idea, and is in fact the coordinator, does not in any way relate to the individual worker as his instrument; but rather he himself exists as an animated individual punctuation mark; as its living isolated accessory. Thus, combined labour is combination *in-itself* in a double way; not combination as a mutual relation among the individuals working together, nor as their predominance either over their particular or individual function or over the instrument of labour. Hence, just as the worker relates to the product of his labour as an alien thing, so does he relate to the combination of labour as an alien combination, as well as to his own labour as an expression of his life, which, although it belongs to him, is alien to him and coerced from him, and which A. Smith etc. therefore conceives is a *burden, sacrifice* etc. [61] Labour itself, like its product, is *negated as the labour of the particular, isolated worker.* This isolated labour, negated, is now indeed communal or combined labour, posited. The *communal or combined labour* posited in this way – as activity and in the passive, objective form – is however at the same time posited as an other towards the really existing individual labour – as an *alien objectivity* (alien property) as well as an *alien subjectivity* (of capital). Capital thus represents both labour and its product as negated individualized labour and hence as the negated property of the individualized worker. Capital therefore is the existence of social labour – the combination of labour as subject as well as object – but this existence as itself existing independently opposite its real moments – hence itself a *particular* existence apart from them. For its part, capital therefore appears as the predominant subject and owner of *alien labour*, and its relation is itself as complete a contradiction as is that of wage labour.>

Forms which precede capitalist production. (Concerning the process which precedes the formation of the capital relation or of original accumulation)

A presupposition of wage labour, and one of the historic preconditions for capital, is free labour and the exchange of this free labour for money, in order to reproduce and to realize money, to consume the use value of labour not for individual consumption, but as use value for money. Another presupposition is the separation of free labour from the objective conditions of its realization – from the means of labour and the material for labour. Thus, above all, release of the worker from the soil as his natural workshop – hence dissolution of small, free landed property as well as of communal landownership resting on the oriental commune. In both forms, the worker relates to the objective conditions of his labour as to his property; this is the natural unity of labour with its material [*sachlich*] presuppositions. The worker thus has an objective existence independent of labour. The individual relates to himself as proprietor, as master of the conditions of his reality. He relates to the others in the same way and – depending on whether this *presupposition* is posited as proceeding from the community or from the individual families which constitute the commune – he relates to the others as co-proprietors, as so many incarnations of the common property, or as independent proprietors like himself, independent private proprietors – beside whom the previously all-absorbing and all-predominant communal property is itself posited as a particular *ager publicus* [62] alongside the many private landowners.

In both forms, the individuals relate not as workers but as proprietors – and members of a community, who at the same time work. The aim of this work is not the *creation of value* – although they may do surplus labour in order to obtain *alien*, i.e. surplus products in exchange – rather, its aim is sustenance of the individual proprietor and of his family, as well as of the total community. The positing of the individual as a *worker,* in this nakedness, is itself a product of *history.*

In the first form of this landed property, an initial, naturally arisen spontaneous [*naturwüchsiges*] community appears as first presupposition. Family, and the family extended as a clan [*Stamm*], [63] or through intermarriage between families, or combination of clans. Since we may assume that *pastoralism,* or more generally a *migratory* form of life, was the first form of the mode of existence, not that the clan settles in a specific site, but that it grazes off what it finds – humankind is not settlement-prone by nature (except possibly in a natural environment so especially fertile that they sit like monkeys on a tree; else roaming like the animals) – then the *clan community,* the natural community, appears not as a *result* of, but as a *presupposition for the communal appropriation* (temporary) *and utilization of the land.* When they finally do settle down, the extent to which this original community is modified will depend on various external, climatic, geographic, physical etc. conditions as well as on their particular natural predisposition – their clan character. This naturally arisen clan community, or, if one will, pastoral society, is the first presupposition – the communality [*Gemeinschaftlichkeit*] of blood, language, customs – for the *appropriation of the objective conditions* of their life, and of their life's reproducing and objectifying activity (activity as herdsmen, hunters, tillers etc.). The earth is the great workshop, the arsenal which furnishes both means and material of labour, as well as the seat, the *base* of the community. They relate naïvely to it as the *property of the community,* of the community producing and reproducing itself in living labour. Each individual conducts himself only as a link, as a member of this community as *proprietor* or *possessor.* The *real appropriation* through the labour process happens under these *presuppositions,* which are not themselves the *product* of labour, but appear as its natural or *divine* presuppositions. This form, with the same land-relation as its foundation, can realize itself in very different ways. E.g. it is not in the least a contradiction to it that, as in most of the *Asiatic* land-forms, the *comprehensive unity* standing above all these little communities appears as the higher *proprietor* or as the *sole proprietor;* the real communities hence only as *hereditary* possessors. Because the *unity* is the real proprietor and the real presupposition of communal property, it follows that this unity can appear as a *particular* entity above the many real particular communities, where the individual is then in fact propertyless, or, property – i.e. the relation of the individual to the *natural* conditions of labour and of reproduction as belonging to him, as the objective, nature-given inorganic body of his subjectivity – appears mediated for him through a cession by the total unity – a unity realized in the form of the despot, the father of the many communities – to the individual, through the mediation of the particular commune. The surplus product – which is, incidentally, determined by law in consequence of the real appropriation through labour – thereby automatically belongs to this highest unity. Amidst oriental despotism and the propertylessness which seems legally to exist there, this clan or communal property exists in fact as the foundation, created mostly by a combination of manufactures and agriculture within the small commune, which thus becomes altogether self-sustaining, and contains all the conditions of reproduction and surplus production within itself. A part of their surplus labour belongs to the higher community, which exists ultimately as a *person,* and this surplus labour takes the form of tribute etc., as well as of common labour for the exaltation of the unity, partly of the real despot, partly of the imagined clan-being, the god. Now, in so far as it actually realizes itself in labour, this kind of communal property can appear either in the form where the little communes vegetate independently alongside one another, and where, inside them, the individual with his family work independently on the lot assigned to them (a certain amount of labour for the *communal reserves, insurance* so to speak, and to *meet the expenses of the community as such,* i.e. for war, religion etc.; this is the first occurrence of the lordly *dominium* in the most original sense, e.g. in the Slavonic communes, in the Rumanian etc. Therein lies the transition to villeinage [*Frondienst*] etc.); or the unity may extend to the communality of labour itself, which may be a formal system, as in Mexico, Peru especially, among the early Celts, a few clans of India. The communality can, further, appear within the clan system more in a situation where the unity is represented in a chief of the clan-family, or as the relation of the patriarchs among one another. Depending on that, a more despotic or a more democratic form of this community system. The communal conditions of real appropriation through labour, *aqueducts,* very important among the Asiatic peoples; means of communication etc. then appear as the work of the higher unity – of the despotic regime hovering over the little communes. Cities proper here form alongside these villages only at exceptionally good points for external trade; or where the head of the state and his satraps exchange their revenue (surplus product) for labour, spend it as labour-fund.

The second form – and like the first it has essential modifications brought about locally, historically etc. – product of more active, historic life, of the fates and modifications of the original clans – also assumes the *community* as its first presupposition, but not, as in the first case, as the substance of which the individuals are mere accidents, or of which they form purely natural component parts – it presupposes as base not the countryside, but the town as an already created seat (centre) of the rural population (owners of land). The cultivated field here appears as a *territorium* belonging to the town; not the village as mere accessory to the land. The earth in itself – regardless of the obstacles it may place in the way of working it, really appropriating it – offers no resistance to [attempts to] relate to it as the inorganic nature of the living individual, as his workshop, as the means and object of labour and the means of life for the subject. The difficulties which the commune encounters can arise only from other communes, which have either previously occupied the land and soil, or which disturb the commune in its own occupation. War is therefore the great comprehensive task, the great communal labour which is required either to occupy the objective conditions of being there alive, or to protect and perpetuate the occupation. Hence the commune consisting of families initially organized in a warlike way – as a system of war and army, and this is one of the conditions of its being there as proprietor. The concentration of residences in the town, basis of this bellicose organization. The clan system in itself leads to higher and lower ancestral lineages [*Geschlechtern*], [64] a distinction which is still further developed through intermixture with subjugated clans etc. Communal property – as state property, *ager publicus* – here separated from private property. The property [*Eigentum*] of the individual is here not, unlike the first case, itself directly communal property; where it is, the individual has no property as distinct from the commune, but rather is merely its possessor [*Besitzer*]. The less it is the case that the individual's property can in fact be realized solely through communal labour – thus e.g. the aqueducts in the Orient – the more the purely naturally arisen, spontaneous character of the clan has been broken by historic movement, migration; the more, further, the clan removes itself from its original seat and occupies *alien* ground, hence enters into essentially new conditions of labour, and develops the energy of the individual more – its common character appearing, necessarily, more as a negative unity towards the outside – the more, therefore, are the conditions given under which the individual can become a *private proprietor* of land and soil – of a particular plot – whose particular cultivation falls to him and his family. The commune – as state – is, on one side, the relation of these free and equal private proprietors to one another, their bond against the outside, and is at the same time their safeguard. The commune here rests as much on the fact that its members consist of working landed proprietors, small-owning peasants, as the peasants' independence rests on their mutual relations as commune members, on protection of the *ager publicus* for communal needs and communal glory etc. Membership in the commune remains the presupposition for the appropriation of land and soil, but, as a member of the commune, the individual is a private proprietor. He relates to his private property as land and soil, but at the same time as to his being as commune member; and his own sustenance as such is likewise the sustenance of the commune, and conversely etc. The commune, although already a *product of history* here, not only in fact but also known as such, and therefore *possessing an origin,* is the presupposition of *property* in land and soil – i.e. of the relation of the working subject to the natural presuppositions of labour as belonging to him – but this belonging [is] mediated by his being a member of the state, by the being of the state – hence by a *presupposition* regarded as divine etc. [65] Concentration in the town, with the land as *territorium;* small agriculture working for direct consumption; manufacture as domestic side occupation of wives and daughters (spinning and weaving) or, independently, in individual branches only *(fabri* [66] etc.). The presupposition of the survival of the community is the preservation of equality among its free self-sustaining peasants, and their own labour as the condition of the survival of their property. They relate as proprietors to the natural conditions of labour; but these conditions must also constantly be posited as real conditions and objective elements of the personality of the individual, by means of personal labour. On the other side, the tendency of this small bellicose community system drives beyond these barriers etc. (Rome, Greece, Jews etc.). 'When the auguries', Niebuhr says, 'had assured Numa of the divine sanction of his election, the pious king's first concern was not worship at the temple, but a human one. He divided the lands which Romulus had won in war and given over to occupation: he endowed the order of Terminus. All the law-givers of antiquity, Moses above all, founded their success in commanding virtue, integrity and proper custom on landed property, or at least on secured, hereditary possession of land, for the greatest possible number of citizens.' (Vol. I, 245, 2nd edition. *Röm. Gesch.*) [67] The individual is placed in such conditions of earning his living as to make not the acquiring of wealth his object, but self-sustenance, his own reproduction as a member of the community; the reproduction of himself as proprietor of the parcel of ground, and, in that quality, as a member of the commune. The survival of the commune is the reproduction of all of its members as self-sustaining peasants, whose surplus time belongs precisely to the commune, the work of war etc. The property in one's own labour is mediated by property in the condition of labour – the hide of land, guaranteed in its turn by the existence of the commune, and that in turn by surplus labour in the form of military service etc. by the commune members. It is not cooperation in wealth-producing labour by means of which the commune member reproduces himself, but rather cooperation in labour for the communal interests (imaginary and real), for the upholding of the association inwardly and outwardly. Property is *quiritorium,* [68] of the Roman variety; the private proprietor of land is such only as a Roman, but as a Roman he is a private proprietor of land.

A[nother] form of the property of working individuals, self-sustaining members of the community, in the natural conditions of their labour, is the *Germanic.* Here the commune member is neither, as such, a co-possessor of the communal property, as in the specifically oriental form (wherever property exists *only* as communal property, there the individual member is as such only *possessor* of a particular part, hereditary or not, since any fraction of the property belongs to no member for himself, but to him only as immediate member of the commune, i.e. as in direct unity with it, not in distinction to it. This individual is thus only a possessor. What exists is only *communal* property, and only *private possession.* The mode of this possession in relation to the communal property may be historically, locally etc. modified in quite different ways, depending on whether labour itself is performed by the private possessor in isolation, or is in turn determined by the commune or by the unity hovering above the particular commune); nor is the situation such as obtains in the Roman, Greek form (in short, the form of classical antiquity) – in this case, the land is occupied by the commune, Roman land; a part remains to the commune as such as distinct from the commune members, *ager publicus* in its various forms; the other part is divided up and each parcel of land is Roman by virtue of being the private property, the domain of a Roman, the part of the *laboratorium* belonging to him; but, also, he is a Roman only in so far as he possesses this sovereign right over a part of the Roman earth. <In antiquity,

urban occupation and trade little esteemed, agriculture, however, highly; in the Middle Ages the contrary appraisal.> <The right of *using* the communal land through *possession* originally appertained to the patricians, who then granted it to their clients; the *transfer of property* out of the *ager publicus* appertained exclusively to the plebeians; all assignments in favour of the plebeians and compensation for a share of the communal property. *Actual property in land,* excepting the area around the city walls, originally only in the hands of the plebeians (rural communes included later.)> <Basis of the Roman plebs as a totality of agriculturists, as is indicated in their quiritary property. Antiquity unanimously esteemed agriculture as the *proper occupation* of the free man, the soldier's school. In it the ancestral stock of the nation sustains itself; it changes in the cities, where alien merchants and dealers settle, just as the indigenous move where gain entices them. Wherever there is slavery, the freedman seeks his support in such dealings, in which he then often gathers riches: thus these occupations were mostly in their hands in antiquity, and were therefore not proper for a citizen: hence the opinion that admission of the craftsmen to full citizenship rights would be a risky undertaking (among the earlier Greeks they were as a rule excluded). 'ὀὐδενὶ γὰρ ἐξῆν ̔Ρωμαίων οὔτε κάπηλον οὔτε χειροτέχνην βίον ἔχειν.' [69] Antiquity had no inkling of a privileged guild-system such as prevailed in the history of medieval cities; and already here the martial spirit declined as the guilds defeated the aristocratic lineages, and was finally extinguished altogether; and consequently, with it, the cities' external respect and freedom.> <The clans of the ancient states were founded on two different principles, either on *ancestry* [*Geschlecht*] or on the *locality.* The *ancestral clans* preceded the locality clans in time and are almost everywhere pushed aside by the latter. Their most extreme, strictest form is the caste-order, in which one is separated from the other, without the right of intermarriage, quite different in [degree of] privilege; each with an exclusive, irrevocable occupation. The *locality clans* originally corresponded to a partition of the countryside into districts and villages; so that someone residing in a given village at the time of this partition, in Attica under Cleisthenes, was registered as a *demotes* (villager) of that village, and as a member of the *phylon* (tribe) of the village's region. Now, his descendants, as a rule, remained in the same *phylon* and the same *demos* without regard to

their residence; whereby this partition also took on an ancestral appearance.> <These Roman *gens* not blood relatives; to the communal name, Cicero adds descent from free men as a sign. Communal *sacra* (shrines) for the Roman gentiles; later ceased (already in Cicero’s time). Practice of co-gentile inheritance, in cases without dependents or will, survived longest of all. In the earliest periods, obligation of all members of the *gens* to help those of their own who require this, to carry unaccustomed burdens. (This occurs originally everywhere among the Germans, remains longest among the Dithmarschen.) The *gentes,* corporations [*Innungen*]. There was in the world of antiquity no more general institution than that of kin groups. Thus among the Gaels the noble Campbells and their vassals forming one clan.> [70] Since the patrician represents the community in a higher degree, he is the *possessor* of the *ager publicus* and uses it through his clients etc. (and also appropriates it little by little). The Germanic commune is not concentrated in the town; by means of such a concentration – the town as centre of rural life, residence of the agricultural workers, likewise the centre of warfare – the commune as such would have a merely outward existence, distinct from that of the individual. The history of classical antiquity is the history of cities, but of cities founded on landed property and on agriculture; Asiatic history is a kind of indifferent unity of town and countryside (the really large cities must be regarded here merely as royal camps, as works of artifice [*Superfötation*] erected over the economic construction proper); the Middle Ages (Germanic period) begins with the land as the seat of history, whose further development then moves forward in the contradiction between town and countryside; the modern [age] is the urbanization of the countryside, not ruralization of the city as in antiquity.

NOTEBOOK V

22 January – Beginning of February 1858

The Chapter on Capital (continuation)

With its coming-together in the city, the commune possesses an economic existence as such; the city’s mere *presence,* as such, distinguishes it from a mere multiplicity of independent houses. The whole, here, consists not merely of its parts. It is a kind of independent organism. Among the Germanic tribes, where the individual family chiefs settled in the forests, long distances apart, the commune exists, already from *outward* observation, only in the periodic gathering-together [*Vereinigung*] of the commune members, although their unity-*in-itself* is posited in their ancestry, language, common past and history, etc. The *commune* thus appears as a *coming-together* [*Vereinigung*], not as a *being-together* [*Verein*]; as a unification made up of independent subjects, landed proprietors, and not as a unity. The commune therefore does not in fact exist as a *state* or *political body,* as in classical antiquity, because it does not exist as a *city.* For the commune to come into real existence, the free landed proprietors have to hold a *meeting,* whereas e.g. in Rome it *exists* even apart from these assemblies in the existence of the *city itself* and of the officials presiding over it etc. True, the *ager publicus,* the communal or people’s land, as distinct from individual property, also occurs among the Germanic tribes. It takes the form of hunting land, grazing land, timber land etc., the part of the land which cannot be divided if it is to serve as means of production in this specific form. But this *ager publicus* does not appear, as with the Romans e.g., as the particular economic presence of the state as against the private proprietors, so that these latter are actually *private* proprietors as such, in so far as they are *excluded,* deprived, like the plebeians, from using the *ager publicus*. Among the Germanic tribes, the *ager publicus* appears rather merely as a complement to individual property, and figures as property only to the extent that it is defended militarily as the common property of one tribe against a hostile tribe. Individual property does not appear mediated by the commune; rather, the existence of the commune and of communal property appear as mediated by, i.e. as a relation of, the independent subjects to one another. The economic totality is, at bottom, contained in each individual household, which forms an independent centre of production for itself (manufactures purely as domestic secondary task for women etc.). In the world of antiquity, the city with its territory is the economic totality; in the Germanic world, the totality is the individual residence, which itself appears as only a small dot on the land belonging to it, and which is not a concentration of many proprietors, but the family as independent unit. In the Asiatic form (at least, predominantly), the individual has no property but only possession; the real proprietor, proper, is the commune – hence property only as *communal property* in land. In antiquity (Romans as the most classic example, the thing in its purest, most fully developed form), the form of state property in land and that of private property in land [are] antithetical, so that the latter is mediated by the former, or the former itself exists in this double form. The private proprietor of land hence at the same time urban citizen. Urban citizenship resolves itself economically into the simple form that the agriculturist [is a] resident of a city. In the Germanic form, the agriculturist not citizen of a state, i.e. not inhabitant of a city; [the] basis [is] rather the isolated, independent family residence, guaranteed by the bond with other such family residences of the same tribe, and by their occasional coming-together [*Zusammnenkommen*] to pledge each others' allegiance in war, religion, adjudication etc. Individual landed property here appears neither as a form antithetical to the commune's landed property, nor as mediated by it, but just the contrary. The commune exists only in the interrelations among these individual landed proprietors as such. Communal property as such appears only as a communal accessory to the individual tribal seats and the land they appropriate. The commune is neither the substance of which the individual appears as a mere accident; nor is it a generality with a *being and unity* as such [*seiende Einheit*] either in the mind and in the existence of the city and of its civic needs as distinct from those of the individual, or in its civic land and soil as its particular presence as distinct from the particular economic presence of the commune member; rather, the commune, on the one side, is presupposed in-itself prior to the individual proprietors as a communality of language, blood etc., but it exists as a presence, on the other hand, only in its *real assembly* for communal purposes; and to the extent that it has a particular economic existence in the hunting and grazing lands for communal use, it is so used by each individual proprietor as such, not as representative of the state (as in Rome); it is really the common property of the individual proprietors, not of the union of these proprietors endowed with an existence separate from themselves, the city itself.

The main point here is this: In all these forms – in which landed property and agriculture form the basis of the economic order, and where the economic aim is hence the production of use values, i.e. the *reproduction of the individual* within the specific relation to the commune in which he is its basis – there is to be found: (1) Appropriation not through labour, but presupposed to labour; appropriation of the natural conditions of labour, of the *earth* as the original instrument of labour as well as its workshop and repository of raw materials. The individual relates simply to the objective conditions of labour as being his; [relates] to them as the inorganic nature of his subjectivity, in which the latter realizes itself; the chief objective condition of labour does not itself appear as a *product* of labour, but is already there as *nature;* on one side the living individual, on the other the earth, as the objective condition of his reproduction; (2) but this *relation* to land and soil, to the earth, as the property of the labouring individual – who thus appears from the outset not merely as labouring individual, in this abstraction, but who has an *objective mode of existence* in his ownership of the land, an existence *presupposed* to his activity, and not merely as a result of it, a presupposition of his activity just like his skin, his sense organs, which of course he also reproduces and develops etc. in the life process, but which are nevertheless presuppositions of this process of his reproduction – is instantly mediated by the naturally arisen, spontaneous, more or less historically developed and modified presence of the individual as *member of a commune* – his naturally arisen presence as member of a tribe etc. An isolated individual could no more have property in land and soil than he could speak. He could, of course, live off it as substance, as do the animals. The relation to the earth as property is always mediated through the occupation of the land and soil, peacefully or violently, by the tribe, the commune, in some more or less naturally arisen or already historically developed form. The individual can never appear here in the dot-like isolation [*Punktualität*] in which he appears as mere free worker. If the objective conditions of his labour are presupposed as belonging to him, then he himself is subjectively presupposed as member of a commune, through which his relation to land and soil is mediated. His relation to the objective conditions of labour is mediated through his presence as member of the commune; at the same time, the real presence of the commune is determined by the specific form of the individual's property in the objective conditions of labour. Whether this property mediated by commune-membership appears as *communal property,* where the individual is merely the possessor and there is no private property in land and soil – or whether property appears in the double form of state and private property alongside one another, but so that the latter appears as posited by the former, so that only the citizen is and must be a private proprietor, while his property as citizen has a separate, particular existence at the same time – or whether, finally, the communal property appears only as a complement to individual property, with the latter as the base, while the commune has no existence for-itself except in the *assembly* of the commune members, their coming-together for common purposes – these different forms of the commune or tribe members' relation to the tribe's land and soil – to the earth where it has settled – depend partly on the natural inclinations of the tribe, and partly on the economic conditions in which it relates as proprietor to the land and soil in reality, i.e. in which it appropriates its fruits through labour, and the latter will itself depend on climate, physical make-up of the land and soil, the physically determined mode of its exploitation, the relation with hostile tribes or neighbour tribes, and the modifications which migrations, historic experiences etc. introduce. The survival of the commune as such in the old mode requires the reproduction of its members in the presupposed objective conditions. Production itself, the advance of population (this too belongs with production), necessarily suspends these conditions little by little; destroys them instead of reproducing them etc., and, with that, the communal system declines and falls, together with the property relations on which it was based. The Asiatic form necessarily hangs on most tenaciously and for the longest time. This is due to its presupposition that the individual does not become independent *vis-à-vis* the commune; that there is a self-sustaining circle of production, unity of agriculture and manufactures, etc. If the individual changes his relation to the commune, he thereby changes and acts destructively upon the commune; as on its economic presupposition; on the other side, the alteration of this economic presupposition brought about by its own dialectic – impoverishment etc. In particular, the influence of warfare and of conquest, which e.g. in Rome belonged to the essential conditions of the commune itself, suspends the real bond on which it rests. In all these forms, the *reproduction of presupposed* relations – more or less naturally arisen or historic as well, but become traditional – of the individual to his commune, together with a *specific, objective* existence, *predetermined* for the individual, of his relations both to the conditions of labour and to his co-workers, fellow tribesmen etc. – are the foundation of development, which is therefore from the outset *restricted,* but which signifies decay, decline and fall once this barrier is suspended. Thus among the Romans, the development of slavery, the concentration of land possession, exchange, the money system, conquest etc., although all these elements up to a certain point seemed compatible with the foundation, and in part appeared merely as innocent extensions of it, partly grew out of it as mere abuses. Great developments can take place here within a specific sphere. The individuals may appear great. But there can be no conception here of a free and full development either of the individual or of the society, since such development stands in contradiction to the original relation.

Do we never find in antiquity an inquiry into which form of landed property etc. is the most productive, creates the greatest wealth? Wealth does not appear as the aim of production, although Cato may well investigate which manner of cultivating a field brings the greatest rewards, and Brutus may even lend out his money at the best rates of interest. [1] The question is always which mode of property creates the best citizens. Wealth appears as an end in itself only among the few commercial peoples – monopolists of the carrying trade – who live in the pores of the ancient world, like the Jews in medieval society. Now, wealth is on one side a thing, realized in things, material products, which a human being confronts as subject; on the other side, as value, wealth is merely command over alien labour not with the aim of ruling, but with the aim of private consumption etc. It appears in all forms in the shape of a thing, be it an object or be it a relation mediated through the object, which is external and accidental to the individual. Thus the old view, in which the human being appears as the aim of production, regardless of his limited national, religious, political character, seems to be very lofty when contrasted to the modern world, where production appears as the aim of mankind and wealth as the aim of production. In fact, however, when the limited bourgeois form is stripped away, what is wealth other than the universality of individual needs, capacities, pleasures, productive forces etc., created through universal exchange? The full development of human mastery over the forces of nature, those of so-called nature as well as of humanity's own nature? The absolute working-out of his creative potentialities, with no presupposition other than the previous historic development, which makes this totality of development, i.e. the development of all human powers as such the end in itself, not as measured on a *predetermined yardstick?* Where he does not reproduce himself in one specificity, but produces his totality? Strives not to remain something he has become, but is in the absolute movement of becoming? In bourgeois economics – and in the epoch of production to which it corresponds – this complete working-out of the human content appears as a complete emptying-out, this universal objectification as total alienation, and the tearing-down of all limited, one-sided aims as sacrifice of the human end-in-itself to an entirely external end. This is why the childish world of antiquity appears on one side as loftier. On the other side, it really is loftier in all matters where closed shapes, forms and given limits are sought for. It is satisfaction from a limited standpoint; while the modern gives no satisfaction; or, where it appears satisfied with itself, it is *vulgar.*

What Mr Proudhon calls the *extra-economic* origin of property, by which he understands just landed property, [2] is the *pre-bourgeois* relation of the individual to the objective conditions of labour, and initially to the *natural* objective conditions of labour – for, just as the working subject appears naturally as an individual, as natural being – so does the first objective condition of his labour appear as nature, earth, as his inorganic body; he himself is not only the organic body, but also the subject of this inorganic nature. This condition is not his product but something he finds to hand – presupposed to him as a natural being apart from him. Before we analyse this further, one more point: the worthy Proudhon would not only be able to, but would have to, accuse *capital* and *wage labour* – as forms of property – of having an *extra-economic* origin. For the encounter with the objective conditions of labour as separate from him, as *capital* from the worker's side, and the encounter with the *worker* as propertyless, as an abstract worker from the capitalist's side – the exchange such as takes place between value and living labour, presupposes a *historic process,* no matter how much capital and labour themselves reproduce this relation and work out its objective scope, as well as its depth – a historic process, which, as we saw, forms the history of the origins of capital and wage labour. In other words: the *extra-economic origin* of property means nothing else than the *historic origin* of the bourgeois economy, of the forms of production which are theoretically or ideally expressed by the categories of political economy. But the fact that pre-bourgeois history, and each of its phases, also has its own *economy* and an *economic foundation* for its movement, is at bottom only the tautology that human life has since time immemorial rested on production, and, in one way or another, on *social* production, whose relations we call, precisely, economic relations.

The original conditions of production (or, what is the same, the reproduction of a growing number of human beings through the natural process between the sexes; for this reproduction, although it appears as appropriation of the objects by the subjects in one respect, appears in another respect also as formation, subjugation of the objects to a subjective purpose; their transformation into results and repositories of subjective activity) *cannot themselves* originally *be products* – results of production. It is not the *unity* of living and active humanity with the natural, inorganic conditions of their metabolic exchange with nature, and hence their appropriation of nature, which requires explanation or is the result of a historic process, but rather the *separation* between these inorganic conditions of human existence and this active existence, a separation which is completely posited only in the relation of wage labour and capital. In the relations of slavery and serfdom this separation does not take place; rather, one part of society is treated by the other as itself merely an *inorganic and natural* condition of its own reproduction. The slave stands in no relation whatsoever to the objective conditions of his labour; rather, *labour* itself, both in the form of the slave and in that of the serf, is classified as *an inorganic condition* of production along with other natural beings, such as cattle, as an accessory of the earth. In other words: the original conditions of production appear as natural presuppositions, *natural conditions of the producer's existence* just as his living body, even though he reproduces and develops it, is originally not posited by himself, but appears as the *presupposition of his self;* his own (bodily) being is a natural presupposition, which he has not posited. These *natural conditions of existence,* to which he relates as to his own inorganic body, are themselves double: (1) of a subjective and (2) of an objective nature. He finds himself a member of a family, clan, tribe etc. – which then, in a historic process of intermixture and antithesis with others, takes on a different shape; and, as such a member, he relates to a specific nature (say, here, still earth, land, soil) as his own inorganic being, as a condition of his production and reproduction. As a natural member of the community he participates in the communal property, and has a particular part of it as his possession; just as, were he a natural Roman citizen, he would have an ideal claim (at least) to the *ager publicus* and a real one to a certain number of *iugera* [3] of land etc. His *property,* i.e. the relation to the natural presuppositions of his production as belonging to him, as *his*, is mediated by his being himself the natural member of a community. (The abstraction of a community, in which the members have nothing in common but language etc., and barely that much, is obviously the product of much later historical conditions.) As regards the individual, it is clear e.g. that he relates even to language itself *as his own* only as the natural member of a human community. Language as the product of an individual is an impossibility. But the same holds for property.

Language itself is the product of a community, just as it is in another respect itself the presence [*Dasein*] of the community, a presence which goes without saying. <Communal production and common property as they exist e.g. in Peru are evidently a *secondary* form; introduced by and inherited from conquering tribes, who, at home, had common property and communal production in the older, simpler form such as is found in India and among the Slavs. Likewise the form which we find among the Celts in Wales e.g. appears as a transplanted, *secondary* form, introduced by conquerors among the lesser, conquered tribes. The completion and systematic elaboration of these systems by a *supreme central authority* shows their later origin. Just as the feudalism introduced into England was more perfect in form than that which arose spontaneously in France.> <Among nomadic pastoral tribes – and all pastoral peoples are originally migratory – the earth appears like other natural conditions, in its elemental limitlessness, e.g. in the Asiatic steppes and the high plateau. It is grazed etc., consumed by the herds, from which the pastoral peoples in turn

live. They relate to it as their property, although they never stabilize this property. This is the case too with the hunting grounds of the wild Indian tribes in America; the tribe regards a certain region as its hunting domain, and asserts it by force against other tribes, or tries to drive others off the domains they assert. Among the nomadic pastoral peoples, the commune is indeed constantly united; the travelling society, the caravan, the horde, and the forms of supremacy and subordination develop out of the conditions of this mode of life. What is in fact *appropriated* and *reproduced* here is not the earth but the herd; but the earth is always used *communally* at each halting place.> The only barrier which the community can encounter in relating to the natural conditions of production – the earth – as to *its own property* (if we jump ahead to the settled peoples) is *another community,* which already claims it as its own inorganic body. *Warfare* is therefore one of the earliest occupations of each of these naturally arisen communities, both for the defence of their property and for obtaining new property. (We can indeed content ourselves here with speaking of land and soil as original property, for among the herding peoples property in natural products of the earth – e.g. sheep – is at the same time property in the pastures they wander through. In general, property in land and soil includes its organic products.) <If human beings themselves are conquered along with the land and soil as its organic accessories, then they are equally conquered as one of the conditions of production, and in this way arises slavery and serfdom, which soon corrupts and modifies the original forms of all communities, and then itself becomes their basis. The simple construction is thereby negatively determined.>

Property thus originally means no more than a human being's relation to his natural conditions of production as belonging to him, as his, as *presupposed* along with *his own being;* relations to them as *natural presuppositions* of his self, which only form, so to speak, his extended body. He actually does not relate to his conditions of production, but rather has a double existence, both subjectively as he himself, and objectively in these natural non-organic conditions of his existence. The forms of these *natural conditions of production* are double: (1) his existence as a member of a community; hence the existence of this community, which in its original form is a *clan* system, a more or less modified *clan* system; (2) the relation to *land*

and soil mediated by the community, as *its own,* as communal landed property, at the same time *individual possession* for the individual, or in such a way that only the fruits are divided, but the land itself and the labour remain common. (However, *residences* etc., even if only the Scythians' wagons, always appear in individual possession.) A natural condition of production for the living individual is his belonging to a *naturally arisen, spontaneous society,* clan etc. This is e.g. already a condition for his language etc. His own productive existence is possible only on this condition. His subjective existence is thereby conditioned as such, just as it is conditioned by his relation to the earth as his workshop. (Property is, it is true, originally *mobile,* for mankind first seizes hold of the ready-made fruits of the earth, among whom belong e.g. the animals, and for him especially the ones that can be tamed. Nevertheless even this situation – hunting, fishing, herding, gathering fruits from trees etc. – always presupposes appropriation of the earth, whether for a fixed residence, or for roaming, or for animal pasture etc.)

Property therefore means *belonging to a clan* (community) (having subjective-objective existence in it); and, by means of the relation of this community to the land and soil, [relating] to the earth as the individual's inorganic body; his relation to land and soil, to the external primary condition of production – since the earth is raw material, instrument and fruit all in one – as to a presupposition belonging to his individuality, as modes of his presence. *We reduce this property to the relation to the conditions of production.* Why not to consumption, since the production of the individual is originally restricted to the reproduction of his own body through the appropriation of ready objects prepared by nature itself for consumption? Even where the only task is to *find* and to *discover,* this soon requires exertion, labour – as in hunting, fishing, herding – and production (i.e. development) of certain capacities on the part of the subject. Then also, situations in which it is possible to seize hold of the things available without any instruments whatever (i.e. products of labour destined for production), without alteration of form (which already takes place for herding) etc., are themselves transitional and in no case to be regarded as normal; nor as normal original situations. The original conditions of production, incidentally, of course include substances consumable directly, without labour; thus the consumption fund appears as s component part of the *original production fund.*

The fundamental condition of property resting on the clan system (into which the community originally resolves itself) – to be a member of the clan – makes the clan conquered by another clan *propertyless* and throws it among the *inorganic conditions* of the conqueror's reproduction, to which the conquering community relates as its own. Slavery and serfdom are thus only further developments of the form of property resting on the clan system. They necessarily modify all of the latter's forms. They can do this least of all in the Asiatic form. In the self-sustaining unity of manufacture and agriculture, on which this form rests, conquest is not so necessary a condition as where *landed property, agriculture* are exclusively predominant. On the other hand, since in this form the individual never becomes a proprietor but only a possessor, he is at bottom himself the property, the slave of him in whom the unity of the commune exists, and slavery here neither suspends the conditions of labour nor modifies the essential relation.

It is now clear, further, that:

Property, in so far as it is only the conscious relation – and posited in regard to the individual by the community, and proclaimed and guaranteed as law – to the conditions of production as *his own,* so that the producer's being appears also in the objective conditions *belonging to him* – is only realized by production itself. The real appropriation takes place not in the mental but in the real, active relation to these conditions – in their real positing as the conditions of his subjective activity.

It is thereby also clear that *these conditions change.* Only when tribes hunt upon it does a region of the earth become a hunting domain; only cultivation of the soil posits the land as the individual's extended body. After the *city of Rome* had been built and the surrounding countryside cultivated by its citizens, the conditions of the community were different from what they had been before. The aim of all these communities is survival; i.e. *reproduction of the individuals who compose it as proprietors, i.e. in the same objective mode of existence as forms the relation among the members and at the same time therefore the commune itself.* This *reproduction, however, is at the same time necessarily new production and destruction of the old form.* For example, where each of the individuals is supposed to possess a given number of acres of land, the advance of population is already under way. If this is to be corrected, then colonization, and that in turn requires wars of conquest. With that, slaves etc. Also, e.g., enlargement of the *ager publicus,* and therewith the patricians who represent the community etc. Thus the preservation of the old community includes the destruction of the conditions on which it rests, turns into its opposite. If it were thought that productivity on the same land could be increased by developing the forces of production etc. (this precisely the slowest of all in traditional agriculture), then the new order would include combinations of labour, a large part of the day spent in agriculture etc., and thereby again suspend the old economic conditions of the community. Not only do the objective conditions change in the act of reproduction, e.g. the village becomes a town, the wilderness a cleared field etc., but the producers change, too, in that they bring out new qualities in themselves, develop themselves in production, transform themselves, develop new powers and ideas, new modes of intercourse, new needs and new language. The older and more traditional the mode of production itself – and this lasts a long time in agriculture; even more in the oriental supplementation of agriculture with manufactures – i.e. the longer the *real process* of appropriation remains constant, the more constant will be the old forms of property and hence the community generally. Where there is already a separation between the commune members as private proprietors [on one side,] and they themselves as the urban commune and proprietors of the commune's *territorium* [on the other], there the conditions already arise in which the individual can *lose* his property, i.e. the double relation which makes him both an equal citizen, a member of the community, and a *proprietor.* In the oriental form this *loss* is hardly possible, except by means of altogether external influences, since the individual member of the commune never enters into the relation of freedom towards it in which he could lose his (objective, economic) bond with it. He is rooted to the spot, ingrown. This also has to do with the combination of manufacture and agriculture, of town (village) and countryside. In classical antiquity, manufacture appears already as a corruption (business for *freedmen,* clients, aliens) etc. This development of productive labour (not bound in pure subordination to agriculture as a domestic task, labour by free men for agriculture or war only, or for religious observances, and manufactures for the community – such as construction of houses, streets, temples), which necessarily develops through intercourse with aliens and slaves, through the desire to exchange the surplus product etc., dissolves the mode of production on which the community rests, and, with it, the *objective individual,* i.e. the individual defined as Roman, Greek, etc. Exchange acts in the same way; indebtedness etc.

The original unity between a particular form of community (clan) and the corresponding property in nature, or relation to the objective conditions of production as a natural being, as an objective being of the individual mediated by the commune – this unity, which appears in one respect as the particular form of property – has its living reality in a specific *mode of production* itself, a mode which appears both as a relation between the individuals, and as their specific active relation to inorganic nature, a specific mode of working (which is always family labour, often communal labour). The community itself appears as the first great force of production; particular kinds of production conditions (e.g. stock-breeding, agriculture), develop particular modes of production and particular forces of production, subjective, appearing as qualities of individuals, as well as objective [ones].

In the last analysis, their community, as well as the property based on it, resolves itself into a specific stage in the development of the productive forces of working subjects – to which correspond their specific relations amongst one another and towards nature. Until a certain point, reproduction. Then turns into dissolution.

Property, then, originally means – in its Asiatic, Slavonic, ancient classical, Germanic form – the relation of the working (producing or self-reproducing) subject to the conditions of his production or reproduction as his own. It will therefore have different forms depending on the conditions of this production. Production itself aims at the reproduction of the producer within and together with these, his objective conditions of existence. This relation as proprietor – not as a result but as a presupposition of labour, i.e. of production – presupposes the individual defined as a member of a clan or community (whose property the individual himself is, up to a certain point). Slavery, bondage etc., where the worker himself appears among the natural conditions of production for a third individual or community (this is *not* the case e.g. with the general slavery of the Orient, *only* from the European point of view) – i.e. property no longer the relation of the working individual to the objective conditions of labour – is always secondary, derived, never original, although [it is] a necessary and logical result of property founded on the community and labour in the community. It is of course very simple to imagine that some powerful, physically dominant individual, after first having caught the animal, then catches humans in order to have them catch animals; in a word, uses human beings as another naturally occurring condition for his reproduction (whereby his own labour reduces itself to ruling) like any other natural creature. But such a notion is stupid – correct as it may be from the standpoint of some particular given clan or commune – because it proceeds from the development of *isolated individuals.* But human beings become individuals only through the process of history. He appears originally as a *species-being* [*Gattungswesen*], *clan being, herd animal* – although in no way whatever as a ζῶον πολιτικόν [4] in the political sense. Exchange itself is a chief means of this individuation [*Vereinzelung*]. It makes the herd-like existence superfluous and dissolves it. Soon the matter [has] turned in such a way that as an individual he relates himself only to himself, while the means with which he posits himself as individual have become the making of his generality and commonness. In this community, the objective being of the individual as proprietor, say proprietor of land, is presupposed, and presupposed moreover under certain conditions which chain him to the community, or rather form a link in his chain. In bourgeois society, the worker e.g. stands there purely without objectivity, subjectively; but the thing which *stands opposite* him has now become the *true community* [*Gemeinwesen*], [5] which he tries to make a meal of, and which makes a meal of him.

All forms (more or less naturally arisen, spontaneous, all at the same time however results of a historic process) in which the community presupposes its subjects in a specific objective unity with their conditions of production, or in which a specific subjective mode of being presupposes the communities themselves as conditions of production, necessarily correspond to a development of the forces of production which is only limited, and indeed limited in principle. The development of the forces of production dissolves these forms, and their dissolution is itself a development of the human productive forces. Labour begins with a certain foundation – naturally arisen, spontaneous, at first – then historic presupposition. Then, however, this foundation or presupposition is itself suspended, or posited as a vanishing presupposition which has become too confining for the unfolding of the progressing human pack.

In so far as classical landed property reappears in modern small-parcel landownership, it itself belongs to political economy and we shall come to it in the section on landed property.

(All this is to be returned to at greater depth and length.)

What we are here concerned with is this: the relation of labour to capital, or to the objective conditions of labour as capital, presupposes a process of history which dissolves the various forms in which the worker is a proprietor, or in which the proprietor works. Thus above all (1) *Dissolution* of the relation to the earth – land and soil – as natural condition of production – to which he relates as to his own inorganic being; the workshop of his forces, and the domain of his will. All forms in which this property appears presuppose a *community,* whose members, although there may be formal distinctions between them, are, as members of it, *proprietors.* The original form of this property is therefore itself *direct common property (oriental form,* modified in the Slavonic; developed to the point of antithesis, but still as the secret, if antithetical, foundation in classical and Germanic property). (2) *Dissolution of the relations* in which he appears as *proprietor of the instrument.* Just as the above form of landed property presupposes a *real community,* so does this property of the worker in the instrument presuppose a particular form of the development of manufactures, namely *craft, artisan work;* bound up with it, the guild-corporation system etc. (The manufacture system of the ancient Orient can be examined under (1) already.) Here labour itself still half artistic, half end-in-itself etc. Mastery. Capitalist himself still master-journeyman. Attainment of particular skill in the work also secures possession of instrument etc. etc. Inheritability then to a certain extent of the mode of work together with the organization of work and the instrument of work. Medieval cities. Labour still as his own; definite self-sufficient development of one-sided abilities etc. (3) Included in both is the fact that he has the means of consumption in his possession before production, which are necessary for him to live as producer –

i.e. during production, *before* its completion. As proprietor of land he appears as directly provided with the necessary consumption fund. As master in a craft he has inherited it, earned it, saved it up, and as a youth he is first an *apprentice,* where he does not appear as an actual independent worker at all, but shares the master's fare in a patriarchal way. As journeyman (a genuine one) there is a certain communality in the consumption fund possessed by the master. While it is not the journeyman's *property* either, still, through the laws of the guild, tradition etc., at least co-possession etc. (To be gone into further.) (4) *Dissolution* likewise at the same time of the relations in which the *workers themselves,* the *living labour capacities* themselves, still belong *directly among the objective conditions of production,* and are appropriated as such – i.e. are slaves or serfs. For capital, the worker is not a condition of production, only work is. If it can make machines do it, or even water, air, so much the better. And it does not appropriate the worker, but his labour – not directly, but mediated through exchange.

These are, now, on one side, historic presuppositions needed before the worker can be found as a free worker, as objectless, purely subjective labour capacity confronting the objective conditions of production as his *not-property,* as *alien property,* as *value* for-itself, as capital. But the question arises, on the other side, which conditions are required so that he finds himself up against a *capital?*

<The formula of capital, where living labour relates to the raw material as well as to the instrument and to the means of subsistence required during labour, as negatives, as not-property, *includes,* first of all, *not-land-ownership,* or, the negation of the situation in which the working individual relates to land and soil, to the earth, as his own, i.e. in which he works, produces, as proprietor of the land and soil. In the best case he relates not only as worker to the land and soil, but also as proprietor of the land and soil to himself as working subject. Ownership of land and soil potentially also includes ownership of the raw material, as well as of the primordial instrument, the earth itself, and of its spontaneous fruits. Posited in the most original form, it means relating to the earth as proprietor, and finding raw material and instrument on hand, as well as the necessaries of life created not by labour but by the earth itself. Once this relation is reproduced, secondary instruments and

fruits of the earth created through labour itself appear as included with landed property in its primitive forms. This historic situation is thus first of all negated as a full property relation, in the worker's relation to the conditions of labour as capital. This is historic state No. I, which is negated in this relation or presupposed as historically dissolved. Secondly, however, where there is *ownership of the instrument* on the part of the worker, i.e. the worker relates to the instrument as his own, where the worker works as owner of the instrument (which at the same time presupposes the subsumption of the instrument under his individual work, i.e. a particular, limited developmental stage of the productive force of labour), where this form of the *worker as owner* or of the *working owner* is already posited as an independent form beside and apart from *landed property* – the artisan-like and urban development of labour – not, as in the first case, as accidental to landed property and subsumed under it – hence where the raw material and the necessaries of life are also *mediated* as the craftsman's property, mediated through his craft work, through his property in the instrument – there a second historical stage is already presupposed beside and apart from the first, which must itself already appear significantly modified, through the *achievement of independence by this second sort of property* or by *working owners.* Since the instrument itself is already the product of labour, thus the element which constitutes property already exists as posited by labour, the community can no longer appear here in a naturally arisen, spontaneous form as in the first case – the community on which this form of property founded – but rather as itself already a produced, made, derived and secondary community, produced by the worker himself. It is clear that wherever ownership of the instrument is the relation to the conditions of production as property, there, in the real labour process, the instrument appears *only as a means* of individual labour; the art of really appropriating the instrument, of handling it as an instrument of labour, appears as the worker's particular skill, which posits him as the owner of the instrument. In short, the essential character of the guild-corporation system, of craft work as its subject, constituted by owners – can be resolved into the relation to the instrument of production – the instrument of labour as property – as distinct from the relation to the earth, to land and soil (to the raw material as such) as one's own. That the relation to this one moment of the conditions of production constitutes the working subject as owner, makes him into a working owner, this [is] historic situation No. II, which by its nature can exist only as antithesis to or, if one will, at the same time as complement of a modified form of the first – likewise negated in the first formula of capital. The third *possible form,* in which the worker relates as owner only to the necessaries of life, finding them on hand as the natural condition of the working subject, without relating to the land and soil, or to the instrument, or even (therefore) to labour itself as his own, is at bottom the formula of slavery and bondage, which is likewise negated, posited as a historically dissolved condition, in the relation of the worker to the conditions of production as capital. The original forms of property necessarily dissolve into the relation to the different objective moments which condition production, as one's own; they form the economic foundation of different forms of community, just as they for their part have specific forms of the community as presupposition. These forms are essentially modified by the inclusion of labour itself among the *objective conditions of production* (serfdom and slavery), through which the simply affirmative character of all forms of property included under No. I is lost and modified. They all contain, within themselves, slavery as possibility and hence as their own suspension. As regards No. II, where the particular kind of work – mastery of it, and, consequent upon that, an identity between property in the instrument and property in the conditions of production – while it excludes slavery and bondage, can take on an analogous negative development in the form of the caste system.> <The third form, ownership of the necessaries of life – if it does not reduce itself to slavery and serfdom – cannot contain a relation by the *working* individual to the conditions of production and hence of existence; it can therefore only be the relation of a member of the original community based on land ownership who has lost his landed property and not yet proceeded to variety No. II of property, such as the Roman *plebs* at the time of the bread and circuses.> <The relation of personal servitude, or of the retainers to their lord, is essentially different. For it forms, at bottom, only a mode of existence of the land-proprietor himself, who no longer works, but whose property includes, among the other conditions of production, the workers themselves as bondsmen etc. Here the *master–servant relation* [*Herrschaftsverhältnis*] as essential element of appropriation. Basically the appropriation of animals, land etc.

cannot take place in a master–servant relation, although the animal provides service. The presupposition of the master–servant relation is the appropriation of an alien *will.* Whatever has no will, e.g. the animal, may well provide a service, but does not thereby make its owner into a *master.* This much can be seen here, however, that the *master–servant relation* likewise belongs in this formula of the appropriation of the instruments of production; and it forms a necessary ferment for the development and the decline and fall of all original relations of property and of production, just as it also expresses their limited nature. Still, it is reproduced – in mediated form – in capital, and thus likewise forms a ferment of its dissolution and is an emblem of its limitation.>

<'The power to sell one's self and one's own when in distress was a grievous general right; it prevailed in the North as well as among the Greeks and in Asia: the power of the creditor to take into servitude a debtor who could not make payment, and to obtain payment through sale of the debtor's labour or of his person, was almost equally widespread.' (Niebuhr, I, p. 600.)> <In one passage Niebuhr says that the Greek writers writing in the period of Augustus had great difficulty with, and misunderstood, the relation between patricians and plebeians, confusing this relation with that between patrons and clients, because they 'write at a time when *rich and poor were the only true classes of citizens;* where the needy person, no matter how noble his ancestry, required a patron, and where the millionaire, even if he were a freed slave, was sought out as a patron. They could hardly find a trace of inherited dependency-relations any longer.' (I, 620.)> <'Craftsmen were to be found in both classes – *Metoikoi* [6] *and freedmen and their descendants* – and the plebeian who abandoned agriculture assumed the limited civic rights to which these were restricted. They did not lack the privilege of *legal corporations;* and their guilds were so highly esteemed, that Numa [7] was named as their founder: they were 9: pipers, gold-smiths, carpenters, dyers, harness makers, tanners, copper-smiths, potters, and the ninth guild, the miscellaneous remainder ... Those among them who were independent citizens; isopolites, [8] who belonged to no patron – if there was such a right; and descendants of servitors, whose bondage was dissolved by extinction of their patron's line; all these people without a doubt remained as distant from the wranglings of the patricians and the commune as did the Florentine guilds from the feuds of the Guelphs and the

Ghibellines: the servitors probably still stood entirely under the command of the patricians.’ (I, 623.)>

On one side, historic processes are presupposed which place a mass of individuals in a nation etc. in the position, if not at first of real free workers, nevertheless of such who are so δυνάμει, whose only property is their labour capacity and the possibility of exchanging it for values then present; individuals who confront all objective conditions of production as *alien property,* as their own *not-property,* but at the same time as *values,* as exchangeable, hence appropriable to a certain degree through living labour. Such historic processes of dissolution are also the dissolution of the bondage relations which fetter the worker to land and soil and to the lord of land and soil; but which factually presuppose his ownership of the necessaries of life – this is in truth the process of his release from the earth; dissolution of the landed property relations, which constituted him as a yeoman, as a free, working small landowner or tenant *(colonus),* a free peasant; * dissolution of the guild relations which presuppose his ownership of the instrument of labour, and which presuppose labour itself as a craftsmanlike, specific skill, as property (not merely as the source of property); likewise dissolution of the client-relations in the various forms in which *not-proprietors* appear in the retinue of their lord as co-consumers of the surplus product and wear the livery of their master as an equivalent, participate in his feuds, perform personal services, imaginary or real etc. It will be seen on closer inspection that all these processes of dissolution mean the dissolution of relations of production in which: use value predominates, production for direct consumption; in which exchange value and its production presupposes the predominance of the other form; and hence that, in all these relations, payments in kind and services in kind predominate over payment in money and money-services. But this only by the way. It will likewise be found on closer observation that all the dissolved relations were possible only with a definite degree of development of the material (and hence also the intellectual) forces of production.

* The dissolution of the still earlier forms of communal property and real community goes without saying.

What concerns us here for the moment is this: the process of dissolution, which transforms a mass of individuals of a nation etc. into free wage labourers δυνάμει – individuals forced solely by their lack of property to labour and to sell their labour – presupposes on the other side *not* that these individuals' previous sources of income and in part conditions of property have *disappeared,* but the reverse, that *only* their utilization has become different, that their mode of existence has changed, has gone over into other hands as a *free fund* or has even in part remained *in the same* hands. But this much is clear: the same process which divorced a mass of individuals from their previous relations to the *objective conditions of labour,* relations which were, in one way or another, affirmative, negated these relations, and thereby transformed these individuals into *free workers,* this same process freed – δυνάμει – these *objective conditions of labour* – land and soil, raw material, necessaries of life, instruments of labour, money or all of these – from their *previous state of attachment* to the individuals now separated from them. They are still *there on hand,* but in another form; as a *free fund,* in which all political etc. relations are obliterated. The objective conditions of labour now confront these unbound, propertyless individuals only in the form of *values,* self-sufficient values. The same process which placed the mass face to face with the *objective conditions of labour* as free workers also placed these conditions, as *capital,* face to face with the free workers. The historic process was the divorce of elements which up until then were bound together; its result is therefore not that one of the elements disappears, but that each of them appears in a negative relation to the other – the (potentially) free worker on the one side, capital (potentially) on the other. The separation of the objective conditions from the classes which have become transformed into free workers necessarily also appears at the same time as the achievement of independence by these same conditions at the opposite pole.

If the relation of capital and wage labour is regarded not as already commanding and predominant over the whole of production, * but as arising historically – i.e. if we regard the original transformation of money into capital, the process of exchange between capital, still only existing δυνάμει on one side and the free workers existing δυνάμει on the other – then of course one cannot help making the simple observation, out of which the economists make a great show, [9] that the side which appears as capital has to possess raw materials, instruments of labour and necessaries of life so that the worker can live during production, before production is completed. This further takes the form that there must have taken place on the part of the capitalist an accumulation – an accumulation prior to labour and not sprung out of it – which enables him to put the worker to work and to maintain his effectiveness, to maintain him as living labour capacity. † This act by capital which is independent of labour, not posited by labour, is then shifted from the prehistory of capital into the present, into a moment of its reality and of its present activity, of its self-formation. From this is ultimately derived the eternal right of capital to the fruits of alien labour, or rather its mode of appropriation is developed out of the simple and just laws of equivalent exchange. [10]

> * For in that case the capital presupposed as condition of wage labour is wage labour's own product, and is presupposed by it as its own presupposition, created by it as its own presupposition.

> † Once capital and wage labour are posited as their own presupposition, as the basis presupposed to production itself, then what appears initially is that the capitalist possesses, in addition to the fund of raw materials and necessaries required for the labourer to reproduce himself, to create the required means of subsistence, i.e. to realize *necessary labour,* a fund of raw material and means of labour in which the worker realizes his surplus labour, i.e. the capitalist's profit. On further analysis this takes the form that the worker constantly creates a double fund for the capitalist, or in the form of capital. One part of this fund constantly fulfils the conditions of his own existence and the other part fulfils the conditions for the existence of capital. As we have seen, in the case of the surplus capital – and surplus capital in relation to its antediluvian relation to labour – all *real, present capital* and each of its elements has equally been *appropriated* without exchange, without an equivalent, as objectified, appropriated *alien labour.*

Wealth present in the form of money can be exchanged for the objective conditions of labour only because and if these are separated from labour itself. We saw that money can be piled up in part by way of the sheer exchange of equivalents; but this forms so insignificant a source that it is not worth mentioning historically – if it is presupposed that this money is gained through the exchange of one's own labour. The monetary wealth which becomes transformed into capital in the proper sense, into industrial capital, is rather the mobile wealth piled up through usury – especially that practised against landed property – and through mercantile profits. We shall have occasion below to speak further of both of these forms – in so far as they appear not as themselves forms of capital, but as earlier forms of wealth, as presuppositions for capital.

It is inherent in the concept of capital, as we have seen – in its origin – that it begins with *money* and hence with wealth existing in the form of money. It is likewise inherent in it that it appears as coming out of circulation, as the *product* of circulation. The formation of capital thus does not emerge from landed property (here at most from the *tenant* [*Pächter*] in so far as he is a dealer in agricultural products); or from the guild (although there is a possibility at the last point); but rather from merchant's and usurer's wealth. But the latter encounter the conditions where free labour can be purchased only when this labour has been released from its objective conditions of existence through the process of history. Only then does it also encounter the possibility of buying these *conditions* themselves. Under guild conditions, e.g., mere money, if it is not itself guild money, masters' money, cannot buy the looms to make people work with them; how many an individual may operate etc. is prescribed. In short, the instrument itself is still so intertwined with living labour, whose domain it appears, that it does not truly circulate. What enables money-wealth to become capital is the encounter, on one side, with free workers; and on the other side, with the necessaries and materials etc., which previously were in one way or another the *property* of the masses who have now become object-less, and are also *free* and purchasable. The other condition of labour, however – a certain level of skill, instrument as means of labour etc. – is already *available* to it in this preliminary or first period of capital, partly as a result of the urban guild system, partly as a result of domestic industry, or industry which is attached to agriculture as an accessory. This historic process is not the product of capital, but the presupposition for it. And it is through this process that the capitalist inserts himself as (historic) middle-man between landed property, or property generally, and labour. History knows nothing of the congenial fantasies according to which the capitalist and the workers form an association etc., nor is there a trace of them in the conceptual development of capital. *Manufactures* may develop sporadically, locally, in a framework which still belongs to a quite different period, as e.g. in the Italian cities *alongside* the guilds. But as the sole predominant forms of an epoch, the conditions for capital have to be developed not only locally but on a grand scale. (Notwithstanding this, individual guild masters may develop into capitalists with the dissolution of the guilds; but the case is rare, in the nature of the thing as well. As a rule, the whole guild system declines and falls, both master and journeyman, where the capitalist and the worker arise.)

It goes without saying – and shows itself if we go more deeply into the historic epoch under discussion here – that in truth the *period of the dissolution* of the earlier modes of production and modes of the workers relation to the objective conditions of labour *is at the same time a period* in which *monetary wealth* on the one side *has* already developed to a certain extent, and on the other side grows and expands rapidly through the same circumstances as accelerate the above dissolution. It is itself one of the agencies of that dissolution, while at the same time that dissolution is the condition of its transformation into capital. But the *mere presence of monetary wealth,* and even the achievement of a kind of supremacy on its part, is in no way sufficient for this *dissolution into capital* to happen. Or else ancient Rome, Byzantium etc. would have ended their history with free labour and capital, or rather begun a new history. There, too, the dissolution of the old property relations was bound up with development of monetary wealth – of trade etc. But instead of leading to industry, this dissolution led in fact to the supremacy of the countryside over the city. – The *original formation* of capital does not happen, as is sometimes imagined, with capital *heaping up* necessaries of life and instruments of labour and raw materials, in short, the *objective* conditions of labour which have already been unbound from the soil and animated by human labour. * Capital does not create the objective conditions of labour. Rather, its *original formation* is that, through the historic process of the dissolution of the old mode of production, value existing as money-wealth is enabled, on one side, *to buy* the objective conditions of labour; on the other side, to exchange money for the *living labour* of the workers who have been set free. All these moments are present; their divorce is itself a historic process, a process of dissolution, and it is *the latter* which enables money to transform itself into *capital.* Money itself, to the extent that it also plays an active role, does so only in so far as it intervenes in this process as itself a highly energetic solvent, and to that extent assists in the creation of the *plucked,* object-less *free workers;* but certainly not by *creating* the objective conditions of their existence; rather by helping to speed up their separation from them – their propertylessness. When e.g. the great English landowners dismissed their retainers, who had, together with them, consumed the surplus product of the land; when further their tenants chased off the smaller cottagers etc., then, firstly, a mass of living labour powers was thereby thrown onto the *labour market,* a mass which was free in a double sense, free from the old relations of clientship, bondage and servitude, and secondly free of all belongings and possessions, and of every objective, material form of being, *free of all property;* dependent on the sale of its labour capacity or on begging, vagabondage and robbery as its only source of income. It is a matter of historic record that they tried the latter first, but were driven off this road by gallows, stocks and whippings, onto the narrow path to the labour market; owing to this fact, the *governments,* e.g. of Henry VII, VIII etc. appear as conditions of the historic dissolution process and as makers of the conditions for the existence of capital. On the other side, the necessaries of life etc., which the landowners previously ate up together with their retainers, now stood at the disposal of any money which might wish to buy them in order to buy labour through their instrumentality. Money neither *created* nor *stockpiled* these necessaries; they were there and were consumed and reproduced before they were consumed and reproduced through its mediation. What had changed was simply this, that these necessaries were now thrown on to the *exchange market* – were separated from their direct connection with the mouths of the retainers etc. and transformed from use values into exchange values, and thus fell into the domain and under the supremacy of money wealth. Likewise with the instruments of labour. Money wealth neither invented nor fabricated the spinning wheel and the loom. But, once unbound from their land and soil, spinner and weaver with their stools and wheels came under the command of money wealth. *Capital proper does nothing but bring together the mass of hands and instruments which it finds on hand. It agglomerates them under its command.* That is its *real stockpiling;* the stockpiling of workers, along with their instruments, at particular points. This will have to be dealt with more closely in the so-called *stockpiling* of capital. Monetary wealth – as merchant wealth – had admittedly helped to speed up and to dissolve the old relations of production, and made it possible for the proprietor of land for example, as A. Smith already nicely develops, [11] to exchange his grain and cattle etc. for use values brought from afar, instead of squandering the use values he himself produced, along with his retainers, and to locate his wealth in great part in the mass of his co-consuming retainers. It gave the *exchange value* of his revenue a higher significance for him. The same thing took place in regard to his tenants, who were already semi-capitalists, but still very hemmed-in ones. The development of exchange value – favoured by *money* existing in the form of the merchant estate – dissolves production which is more oriented towards direct use value and its corresponding forms of property – the relations of labour to its objective conditions – and thus pushes forward towards the making of the *labour market* (certainly to be distinguished from the slave market). However, even this action of money is only possible given the presupposition of an *urban artisanate* resting *not* on capital but on the organization of labour in guilds etc. Urban labour itself had created means of production for which the guilds became just as confining as were the old relations of landownership to an improved agriculture, which was in part itself a consequence of the larger market for agricultural products in the cities etc. The other circumstances which e.g. in the sixteenth century increased the mass of circulating commodities as well as that of money, which created new needs and thereby raised the exchange value of indigenous products etc., raised prices etc., all of these promoted on one side the dissolution of the old relations of production, sped up the separation of the worker or non-worker but able-bodied individual from the objective conditions of his reproduction, and thus promoted the transformation of money into capital. There can therefore be nothing more ridiculous than to conceive this *original formation* of capital as if capital had stockpiled and created the *objective conditions of production* – necessaries, raw materials, instrument – and then offered them to the worker, who was *bare* of these possessions. Rather, monetary wealth in part helped to *strip* the labour powers of able-bodied individuals from these conditions; and in part this process of divorce proceeded without it. When the formation of capital had reached a certain level, monetary wealth could place itself as mediator between the objective conditions of life, thus liberated, and the liberated but also *homeless* and *empty-handed* labour powers, and buy the latter with the former. But now, as far as the *formation of money-wealth* itself is concerned, this belongs to the prehistory of the bourgeois economy. Usury, trade, urbanization and the treasury rising with it play the main roles here. So, too, *hoarding* by tenants, peasants etc.; although to a lesser degree. – This shows at the same time that the development of exchange and of exchange value, which is everywhere mediated through trade, or whose mediation may be termed trade – money achieves an independent existence in the merchant estate, as does circulation in trade – brings with it both the dissolution of *labour's relations of property in its* conditions of existence, in one respect, and at the same time the dissolution of *labour* which is itself *classed as one of the objective conditions of production;* all these are relations which express a predominance of use value and of production directed towards use value, as well as of a real community which is itself still directly present as a presupposition of production. Production based on exchange value and the community based on the exchange of these exchange values – even though they seem, as we saw in the previous chapter on money, to posit property as the outcome of *labour* alone, and to posit private property over the product of one's own labour as condition – and labour as general condition of wealth, all presuppose and produce the separation of labour from its objective conditions. This exchange of equivalents proceeds; it is only the surface layer of a production which rests on the appropriation of alien labour *without exchange,* but with the *semblance of exchange.* This system of exchange rests on *capital* as its foundation, and, when it is regarded in isolation from capital, as it appears on the surface, as an *independent* system, then it is a mere *illusion,* but a *necessary illusion.* Thus there is no longer any ground for astonishment that the system of exchange values – exchange of equivalents measured through labour – turns into, or rather reveals as its hidden background, the *appropriation of alien labour without exchange,* complete separation of labour and property. For the domination of exchange value itself, and of exchange-value-producing production, *presupposes* alien labour capacity itself as an exchange value – i.e. the separation of living labour capacity from its objective conditions; a relation to them – or to its own objectivity – as alien property; a relation to them, in a word, as *capital.* Only in the period of the decline and fall of the feudal system, but where it still struggles internally – as in England in the fourteenth and first half of the fifteenth centuries – is there a golden age for labour in the process of becoming emancipated. In order for labour to relate to its objective conditions as its property again, another system must take the place of the system of private exchange, which, as we saw, posits the exchange of objectified labour for labour capacity, and therefore the appropriation of living labour without exchange. – The way in which money transforms itself into capital often shows itself quite tangibly in history; e.g. when the merchant induces a number of weavers and spinners, who until then wove and spun as a rural, secondary occupation, to work for him, making their secondary into their chief occupation; but then has them in his power and has brought them under his command as wage labourers. To draw them away from their home towns and to concentrate them in a place of work is a further step. In this simple process it is clear that the capitalist has prepared neither the raw material, nor the instrument, nor the means of subsistence for the weaver and the spinner. All that he has done is to restrict them little by little to one kind of work in which they become dependent on selling, on the *buyer,* the *merchant,* and ultimately produce only *for* and *through* him. He bought their labour originally only by buying their product; as soon as they restrict themselves to the production of this exchange value and thus must directly produce *exchange values,* must exchange their labour entirely for money in order to survive, then they come under his command, and at the end even the illusion that they *sold* him products disappears. He buys their labour and takes their property first in the form of the product, and soon after that the instrument as well, or he leaves it to them as *sham property* in order to reduce his own production costs. – The original historic forms in which capital appears at first sporadically or *locally, alongside* the old modes of production, while exploding them little by little everywhere, is on one side *manufacture* proper (not yet the factory); this [12] springs up where mass quantities are produced for export, for the external market – i.e. on the *basis of large-scale overland and maritime commerce,* in its emporiums like the Italian cities, Constantinople, in the Flemish, Dutch cities, a few Spanish ones, such as Barcelona etc. Manufacture seizes hold initially not of the so-called *urban trades,* but of the *rural secondary occupations,* spinning and weaving, the two which least requires guild-level skills, technical training. Apart from these great emporiums, where the external market is its basis, where production is thus, so to speak, *naturally* oriented towards exchange value – i.e. manufactures directly connected with shipping, shipbuilding itself etc. – it takes up its first residence not in the cities, but on the land, in villages lacking guilds etc. The rural subsidiary occupations have the broad basis [characteristic] of manufactures, while the urban trades demand great progress in production before they can be conducted in factory style. Likewise certain branches of production – such as glassworks, metal works, sawmills etc., which demand a higher concentration of labour powers from the outset, apply more natural energy from the outset, demand mass production, likewise concentration of the means of labour etc. Likewise paper mills. On the other side the rise of the tenant and the transformation of the agricultural population into free day-labourers. Although this transformation in the countryside is the last to push on towards its ultimate consequences and its purest form, its beginnings there are among the earliest. Classical antiquity, which could never get beyond the urban artisanate proper, could therefore never get to large industry. The first presupposition of the latter is to draw the land in all its expanse into the production not of use values but of exchange values. Glass factories, paper mills, iron works etc. cannot be operated on guild principles. They demand mass production; sales to a general market; *monetary wealth* on the part of their entrepreneur – not that he creates the conditions, neither the subjective nor the objective ones; but under the old relations of property and of production these conditions cannot be brought together. – The dissolution of relations of serfdom, like the rise of manufacture, then little by little transforms all branches of work into branches operated by capital. – The cities themselves, it is true, also contain an element for the formation of wage labour proper, in the non-guild day-labourers, unskilled labourers etc.

[*] The first glance shows what a nonsensical circle it would be if on the one hand the *workers* whom capital has to put to work in order to posit itself as capital had first to be *created,* to be brought to life through its *stockpiling* if they waited for its command, *Let There Be Workers!;* while at the same time it were itself incapable of *stockpiling* without alien labour, could at most stockpile *its own labour,* i.e. could itself exist in the form of *not-capital* and *not-money;* since labour, before the

> existence of capital, can only realize itself in forms such as craft labour, petty agriculture etc., in short, all forms which can *not stockpile,* or only sparingly; in forms which allow of only a small surplus product and *eat up* most of it. We shall have to examine this notion of *stockpiling* [*Aufhäufung*] still more closely later on.

While, as we have seen, the transformation of money into capital presupposes a historic process which divorces the objective conditions of labour from the worker and makes them independent of him, it is at the same time the effect of capital and of its process, once arisen, to conquer all of production and to develop and complete the divorce between labour and property, between labour and the objective conditions of labour, everywhere. It will be seen in the course of the further development how capital destroys craft and artisan labour, working small-landownership etc., together with itself in forms in which it does *not* appear in opposition to labour – in *small capital* and in the intermediate species, the species between the old modes of production (or their renewal on the foundation of capital) and the classical, adequate mode of production of capital itself.

The only stockpiling presupposed at the origin of capital is that of *monetary wealth,* which, regarded in and for itself, is altogether unproductive, as it only springs up out of circulation and belongs exclusively to it. Capital rapidly forms an internal market for itself by destroying all rural secondary occupations, so that it spins, weaves for everyone, clothes everyone etc., in short, brings the commodities previously created as direct use values into the form of exchange values, a process which comes about by itself through the separation of the workers from land and soil and from property (even in the form of serf property) in the conditions of production.

With the urban crafts, although they rest essentially on exchange and on the creation of exchange values, the direct and chief aim of this production is *subsistence as craftsmen,* as *master-journeymen,* hence use value; not *wealth,* not *exchange value as exchange value.* Production is therefore always subordinated to a given consumption, supply to demand, and expands only slowly.

The *production of capitalists and wage labourers is thus a chief product of capital's realization process.* Ordinary economics, which looks only at the things produced, forgets this completely. When objectified labour is, in this process, at the same time posited as the worker's *non-objectivity,* as the objectivity of a subjectivity antithetical to the worker, as *property* of a will alien to him, then capital is necessarily at the same time the *capitalist,* and the idea held by some socialists that we need capital but not the capitalists is altogether wrong. It is posited within the concept of capital that the objective conditions of labour – and these are its own product – take on a *personality* towards it, or, what is the same, that they are posited as the property of a personality alien to the worker. The concept of capital contains the capitalist. Still, this error is in no way greater than that of e.g. all philologists who speak of *capital* in antiquity, of Roman, Greek capitalists. This is only another way of expressing that labour in Rome and Greece was *free,* which these gentlemen would hardly wish to assert. The fact that we now not only call the plantation owners in America capitalists, but that they *are* capitalists, is based on their existence as anomalies within a world market based on free labour. If the concern is the word, capital, which does not occur in antiquity * then the still migrating hordes with their herds on the Asiatic high plateau are the biggest capitalists, since capital originally means cattle, which is why the *métairie* contract still frequently drawn up in southern France, for lack of capital, just as an exception, is called: *Bail de bestes à cheptel.* [14] If one wants to descend to bad Latin, then our capitalists or *Capitales Homines* would be those '*qui debent censum de capite*'. [15]

---

* Although ἀρχεῖα among the Greeks, corresponding to the *principalis summa rei creditae*. [13]

The conceptual specification of capital encounters difficulties which do not occur with money; capital is essentially *capitalist;* but at the same time again as an element of his existence distinct from him, or production in general, *capital.* We shall likewise find later that many things are subsumed under *capital* which do not seem to belong within it conceptually. E.g. capital is lent out. It is stockpiled etc. In all these designations it appears to be a mere thing, and to coincide entirely with the matter in which it is present. But this and other questions will be cleared up in the course of the development. (Noted incidentally as a joke: the good Adam Müller, who takes all figurative ways of speaking as very mystical, has also heard of *living capital* in ordinary life as opposed to *dead* capital, and now rationalizes this theosophically. [16] King Aethelstan could teach him a lesson here: *Reddam de meo proprio decimas Deo tam in Vivente Capitale* (livestock), *quam in mortis fructuis terrae* (dead fruits of the earth).) [17] Money always remains the same form in the same substratum; and can thus be more easily conceived as a mere thing. But one and the same commodity, money etc., can represent capital or revenue etc. Thus it is clear even to the economists that money is not something tangible; but that one and the same thing can be subsumed sometimes under the title capital, sometimes under another and contrary one, and correspondingly *is* or *is not* capital. It is then evident that it is a *relation, and can only be a relation of production.*

We have seen that the true nature of capital emerges only at the *end of the second cycle.* What we have to examine now is this cycle itself, or the *circulation of capital.* Production originally appeared to lie beyond circulation, and circulation beyond production. The circulation of capital – circulation posited as the circulation of capital – spans both moments. Production appears in it as the conclusion and the point of departure of circulation, and vice versa. The independence of circulation is here reduced to a mere semblance, as is the otherworldliness of production.

Exchange of labour for labour rests on the worker's propertylessness

<But one more remark on the topic above: The exchange of equivalents, which seems to presuppose ownership of the products of one's own labour – hence seems to posit as identical: *appropriation through labour,* the real economic process of making something one's own [*Zueigen-Machen*], and *ownership of objectified* labour; what appeared previously as a real process is here recognized as a legal relation, i.e. as a general condition of production, and therefore recognized by law, posited as an expression of the general will – turns into, reveals itself through a necessary dialectic as absolute divorce of labour and property, and appropriation of alien labour without exchange, without equivalent. Production based on exchange value, on whose surface this free and equal exchange of equivalents proceeds, is at its base the exchange of *objectified labour* as exchange value for living labour as use value, or, to express this in another way, the relating of labour to its objective conditions – and hence to the objectivity created by itself – as alien property: *alienation* [*Entäusserung*] *of labour.* At the same time, the condition of exchange value is its measurement by labour time, and hence living labour – not its value – as measure of values. The notion that production and hence society depended in all states of production on the *exchange of mere labour for labour* is a delusion. In the various forms in which labour relates to the conditions of production as its own property, the reproduction of the worker is by no means posited through *mere labour,* for his property relation is not the result but the presupposition of his labour. In landed property this is clear; it must also become clear in the guild system that the particular kind of property which labour creates does not rest on labour alone or on the exchange of labour, but on an objective connection between the worker and a community and conditions which are there before him, which he takes as his basis. These too are products of labour, of the labour of world history; of the labour of the community – of its historic development, which does not proceed from the labour of individuals nor from the exchange of their labours. Therefore, mere labour is also not the presupposition of realization [*Verwertung*]. A situation in which labour is merely exchanged for labour – whether in the direct, living form, or in the form

of the product – presupposes the separation of labour from its original intertwinement with its objective conditions, which is why it appears as mere labour on one side, while on the other side its product, as objectified labour, has an entirely independent existence as value opposite it. *The exchange of labour for labour – seemingly the condition of the worker's property – rests on the foundation of the worker's propertylessness.>*

(It will be shown later that the *most extreme form of alienation,* wherein labour appears in the relation of capital and wage labour, and labour, productive activity appears in relation to its own conditions and its own product, is a necessary point of transition – and therefore already contains in *itself,* in a still only inverted form, turned on its head, the dissolution of all *limited presuppositions of production,* and moreover creates and produces the unconditional presuppositions of production, and therewith the full material conditions for the total, universal development of the productive forces of the individual.)

Circulation of capital and circulation of money. – Presupposition of value within each single capital (instrument etc.). – Production process and circulation process moments of production. – The productivity of the different capitals (branches of industry) determines that of the individual capital. – Circulation period. Velocity of circulation substitutes for volume of capital. Mutual dependence of capitals in the velocity of their circulation. Circulation a moment of production. Production process and its duration. Transformation of the product into money. Duration of this operation. Retransformation of money into the conditions of production. Exchange of part of the capital with living labour. – Transport costs

The circulation of money began at an infinite number of points and returned to an infinite number of points. The point of return was in no way posited as the point of departure. In the circulation of capital, the point of departure is posited as the terminal point and the terminal point as the point of departure. The capitalist himself is the point of departure and of return. He exchanges money for the conditions of production, produces, realizes the product, i.e. transforms it into money, and then begins the process anew. The circulation of money, regarded for itself, necessarily becomes extinguished in money as a static thing. The circulation of capital constantly ignites itself anew, divides into its different moments, and is a *perpetuum mobile.* The positing of prices on the side of money circulation was purely formal, in so far as *value* is presupposed independently of money circulation. The circulation of capital *posits prices,* not only formally but really, in so far as it posits value. If value itself appears within it as presupposition, this can only be as *value posited* by another capital. The breadth of the path for money circulation has been measured in advance, and the circumstances which accelerate or retard it are external impulses. In its circulation, capital expands itself and its path, and the speed or slowness of its circulation itself forms one of its intrinsic moments. It becomes qualitatively altered in circulation and the totality of the moments of its circulation are themselves the moments of its production – its reproduction as well as its new production.

<We saw how at the end of the second cycle, i.e. the second cycle of surplus value which has been realized as surplus capital, the illusion disappears that the capitalist exchanges anything at all with the worker other than a part of the latter's own objectified labour. [18] However, within the mode of production already founded on capital, the part of capital which represents raw materials and instrument appears to the individual capital as a value *presupposed* to it and likewise presupposed to the *living labour* which it buys. These two headings turn out to have been posited by *alien capital,* hence again by *capital,* but another one. One capitalist's raw material is another's product. One's product is the other's raw material. One capitalist's *instrument* is another's product, and may even serve as raw material for the production of another instrument. Thus, what we called the constant value which appeared as a presupposition in the case of the individual capital is nothing but the presupposition of capital by capital, i.e. the fact that the different capitals in the different branches of industry posit one another reciprocally as presupposition and condition. Each of them regarded for itself can be resolved into dead labour which, as *value,* has *become independent vis-à-vis* living labour. None of them in the last analysis contains anything other than labour – apart from the natural material from which value is absent. The introduction of *many* capitals

must not interfere with the investigation here. The relation of the *many* will, rather, be explained after what they all have in common, the quality of being capital, has been examined.>

The circulation of capital is at the same time its becoming, its growth, its vital process. If anything needed to be compared with the circulation of the blood, it was not the formal circulation of money, but the content-filled circulation of capital.

Since circulation presupposes production at all points – and is the circulation of products, whether money or commodity, while the latter always arise from the production process, which is itself the process of capital – it follows that the circulation of money itself now appears as determined by the circulation of capital, whereas previously it seemed to run *side by side with* the production process. We shall return to this point.

If we now consider circulation, or the circulation of capital as a whole, then the great distinction within it appears to be that between the production process and circulation itself, both as moments of its circulation. How long capital remains within the sphere of the production process depends on the latter's technological conditions, and the time it spends in this phase directly coincides – even though the duration is necessarily different depending on the type of production, its object etc. – with the development of the productive forces. The duration is here nothing but the labour time necessary for the making of the product (false!). [19] The smaller this labour time, the greater, as we have seen, the relative surplus value. If less labour time is required to make a given quantity of products, it is the same thing as if more finished products can be supplied in a given amount of labour time. The abbreviation of the time during which a given amount of capital remains within the production process and is withdrawn from circulation, 'embarked', [20] coincides with the abbreviation of the labour time required to make the product – [therefore coincides] with the development of the forces of production, the utilization of the forces of nature, of machinery, and of the natural powers of social labour – the agglomeration of the workers, the combination and division of labour. Thus no new moment seems to enter in from this side. However, when it is recalled that, as far as the individual capital is concerned, the part of it which constitutes raw material and instrument (means of labour) is itself the product of an alien capital, then it may be seen that the speed with which it can repeat the production process anew is at the same time determined by the development of the productive forces in all other branches of industry. This becomes quite clear if one supposes the same capital to produce its own raw materials, instruments and final products. The length of time during which capital remains in the phase of the production process becomes itself a moment of circulation, if we presuppose *various* capitals. But we are not yet concerned with *many* capitals here. This moment therefore does not belong here.

The second moment is the space of time running from the completed transformation of capital into the product until when it becomes transformed into money. The frequency with which capital can repeat the production process, self-realization, in a given amount of time, evidently depends on the speed with which this space of time is run through, or on its duration. If a capital – say originally a capital of 100 thalers – turns over 4 times in one year; let the gain be 5% of itself each time, if the new value is not capitalized; this is the same as if a capital 4 times as large, say 400, at the same percentage, were to turn over *once* in one year; each time 20%. The velocity of turnover therefore – the remaining conditions of production being held constant – substitutes for the *volume* of capital. Or, if a value 4 times smaller realizes itself as capital 4 times in the same period in which a 4 times greater value realizes itself as capital only once, then the smaller capital's gain – production of surplus value – is *at least as great* as the larger's. We say at least. It can be greater, because the surplus value can itself again be employed as surplus capital. For example, assume that a capital of 100 has a profit (here anticipating *this form* of surplus value for the calculation's sake) of 10% each time, no matter how often it turns over. Then, at the end of the first 3 months, it would be 110, at the end of the second 121, at the end of the third 133 1/10, and at the end of the last turnover 146 41/100, while a capital of 400 with one annual turnover would be only 440. In the first case the gain = 46 41/100, in the second only = 40. (The fact that the presupposition is wrong, in as much as capital does not bring the *same* rate of profit with each increase in its size, is beside the point as far as the example is concerned, for the issue here is not how much more than 40 it brings, but the very fact that in the first case it does – and it does – bring in more than 40.) We have already encountered the law of the substitution of velocity for mass, and mass for velocity, in money circulation. It holds in production just as in mechanics. It is a circumstance to return to when we consider the equalization of the rate of profit, price etc. The question which interests us here is this: Does not a moment of value-determination enter in independently of labour, not arising directly from it, but originating in circulation itself? <The fact that *credit* equalizes the differences in capital turnover does not belong here yet. But the question itself belongs here, because it arises out of the simple concept of capital – regarded in general.> The more frequent turnover of capital in a given period of time resembles the more frequent harvests during the natural year in the southerly countries compared with the northerly. As already stated above, we here abstract entirely from the different amounts of time which capital must spend in the phase of production – in the productive realization process itself. Just as grain when it is put in the soil as seed loses its immediate use value, is *devalued* as immediate use value, so is capital *devalued* from the completion of the production process until its retransformation into money and from there into capital again. <This velocity with which it can transpose itself from the form of money back into the conditions of production – unlike in slavery, it is not the worker himself who appears among these conditions of production, but rather the exchange with him – depends on the production speed and continuity of the remaining capitals, which supply him with raw material and instrument, as well as on the availability of workers, and in this last respect a relative surplus population is the best condition for capital.> <Quite apart from capital A's production process, the speed and continuity of production process B appears as a moment which conditions the retransformation of capital A from the form of money into the form of industrial capital. The duration of the *production process* of capital B thus appears as a moment in the *velocity of the circulation process* of capital A. The duration of one capital's production phase determines the velocity of the other's circulation phase. Their *simultaneity* is a condition required so that A's circulation is not obstructed – the fact that its own elements, for which it has to exchange and be exchanged, are thrown into production and circulation simultaneously. For example. In the final third of the eighteenth century, the hand-spinning system was incapable of supplying the required amounts of raw material for weaving – or, what is the same – spinning

could not put the flax or cotton through its production process with the required simultaneity – simultaneous velocity. The consequence was the invention of the spinning machine, which supplied a greater product in the same labour time, or, what is the same thing, required less labour time for the same product – less time delay in the spinning process. All moments of capital which appear involved in it when it is considered from the point of view of its general concept obtain an independent reality, and, further, only show themselves when it appears as real, as many capitals. The inner, living organization, which takes place in this way within and through competition, thus develops all the more extensively.>

If we examine the entire turnover of capital, then four moments appear, or, each of the two great moments of the production process and the circulation process appears again in a duality: we can take either circulation or production as the point of departure here. This much has now been said, that circulation is itself a moment of production, since capital becomes capital only through circulation; production is a moment of circulation only in so far as the latter is itself regarded as the totality of the production process. The moments are: (I) The real production process and its duration. (II) Transformation of the product into money. Duration of this operation. (III) Transformation of the money in the proper proportions into raw material, means of labour and labour, in short, into the elements of productive capital. (IV) The exchange of a part of the capital for living labour capacity can be regarded as a particular moment, and must be so regarded, since the labour market is ruled by other laws than the product market etc. Here population is the main thing, not in absolute but in relative terms. Moment I does not come into consideration here, as stated, since it coincides with the conditions of realization generally. Moment III can be considered only when the theme is not capital generally, but many capitals. Moment IV belongs in the section on wages etc.

We are concerned here only with Moment II. In money circulation there was a merely formal alternation of exchange value as money and as commodity. Here *money, commodity, are conditions of production,* ultimately of the production process. The moments here are different; they are filled with content. The differences in capital turnover as posited in II – since it depends neither on greater difficulty in the exchange with labour, nor on delays resulting from the fact that raw material [*Rohstoff*] and raw material [*Rohmaterial*] [21] are not present simultaneously in circulation, nor in the different durations of the production process – could therefore arise only from increased difficulties in realization. This is obviously not an immanent case arising from the relation itself, but rather coincides here, where we are examining capital in general, with what we have said about the way in which realization simultaneously results in devaluation. [22] No business will be founded on the principle that it can sell its products with *greater difficulty* than another. If this resulted from the smaller size of the market, then not a larger – as presupposed – but a smaller capital would be employed there than in the business with a larger market. It could be connected, however, with the *greater distance of the market in space* and hence the delayed return. The longer time required by capital A to realize itself would be due here to the greater spatial distance it has to travel after the production process in order to exchange as C for M. But cannot e.g. the product produced for China be regarded in such a way that the product is completed, its production process completed, only when it has reached the Chinese market? Its realization costs would rise by the costs of transport from England to China. (We cannot yet speak about the compensation for the longer fallow period of capital here, because the secondary and derived forms of surplus value – interest – would already have to have been presupposed.) The costs of production would resolve into the labour time objectified in the direct production process + the labour time contained in transport. Now the question is initially this: Given the basic principles we have so far asserted, can a surplus value be extracted from the transport costs? Let us deduct the constant part of the capital consumed in transport, ship, vehicle etc. and everything which falls under the heading of their application, since this element contributes nothing to the question, and it is irrelevant whether this is posited as = 0 or = x. Is it possible, then, that there is surplus labour in these transport costs, and that capital can therefore squeeze a surplus value out of them? The question is simple to answer if we ask a further question, where and which is the necessary labour or the value in which it objectifies itself? The product must pay (1) its own exchange value, the labour objectified in itself; (2) the surplus time, which the shipper, carter etc. employs on its transportation. Whether he can or cannot extract the surplus value depends on the wealth of the country into which he brings the product and on its needs etc., on the use value of the product for this land. In direct production, it is clear that all the surplus labour which the manufacturer makes the worker do is surplus value for him, in that it is labour objectified in new use values, which costs him nothing. But he can obviously not employ him during transport for a longer time than is required for the transporting. Otherwise he would throw labour time away instead of realizing it, i.e. he would not objectify it in a use value. If the sailor, the carter etc. require only half a year of labour time to live a full year (if this is generally the proportion of labour necessary for subsistence), then the capitalist employs him for a whole year and pays him a half. By adding a whole year's labour time to the value of the transported products, but paying only 1/2, he gains a surplus value of 100% on necessary labour. The case is entirely the same as indirect production, and the original surplus value of the transported product can come about only because the workers are *not paid* for a part of the transportation time, because it is surplus time, time *over and above* the labour necessary for them to live. That an individual product might be made so much more expensive, owing to the transport costs, that it could not be sold – on account of the disproportion between the value of the product and its surplus value as a transported product, a quality which becomes extinguished in it as soon as it has arrived at its destination – does not affect the matter. If a manufacturer were to set his entire machinery into motion in order to spin 1 lb. of twist, then the value of this lb. would likewise rise so that it would hardly find a market. The rise in the prices of imported products, as well as the smaller consumption of them in the Middle Ages etc., stem precisely from this cause. Whether I extract metals from mines, or take commodities to the site of their consumption, both movements are equally spatial. The improvement of the means of transport and communication likewise falls into the category of the development of the productive forces generally. The fact that it can depend on the value of the products whether or not they are able to bear transport costs; that, further, commercial traffic in mass quantities is required to reduce transport costs – a ship with a loading capacity of 100 tons can carry 2 or 100 tons with the same transport costs etc. – and in order to make means of communication pay etc., all this does not belong here. (Nevertheless, it will be necessary to devote a special section to the means of communication, since they make up a form of fixed capital which has its own laws of realization.) If one imagines the same capital both producing and transporting, then both acts fall within direct production, and circulation as we have considered it so far, i.e. transformation into money as soon as the product has achieved its final form for consumption, would begin only when the product had been brought to its point of destination. This capitalist’s delayed return compared to that of another, who gets rid of his product on the spot, would resolve into another form of greater use of fixed capital, with which we are not yet concerned here. Whether A requires 100 thalers more for instrument, or whether he needs 100 thalers more in order to bring his product to its destination, to market, is the same thing. In both cases more fixed capital is used; more *means* of production, which is consumed in direct production. In this respect, then, no immanent case would be posited here; it would fall under the examination of the difference between fixed capital and circulating capital.

Circulation costs. – Means of communication and transport. (Division of the branches of labour.) (Concentration *of many workers. Productive force of this concentration.)* (Mass *production.)* – General as distinct from particular conditions of production

Still, an additional moment enters here: the *costs of circulation,* which are not contained in the simple concept of circulation and do not concern us yet. Only in connection with interest and particularly with credit can we speak of the *costs of circulation* arising from circulation as an economic act – as a relation of production, not as a direct moment of production, as was the case with the *means of transport and communication.* Circulation as we regard it here is a process of transformation, a qualitative process of value, as it appears in the different form of money, production (realization) process, product, retransformation into money and surplus capital. [We are concerned here] in so far as new aspects are created within this process of transformation as such – in this transition from one form to another. The costs of circulation are not necessarily included e.g. in the transition from product to money. They can be = 0.

However, in so far as circulation itself creates costs, itself requires surplus labour, it appears as itself included within the production process. In this respect circulation appears as a moment of the direct production process. Where production is directly oriented towards use, and only the excess product is exchanged, the costs of circulation appear only for the excess product, not for the main product. [23] The more production comes to rest on exchange value, hence on exchange, the more important do the physical conditions of exchange – the means of communication and transport – become for the costs of circulation. Capital by its nature drives beyond every spatial barrier. Thus the creation of the physical conditions of exchange – of the means of communication and transport – the annihilation of space by time – becomes an extraordinary necessity for it. Only in so far as the direct product can be realized in distant markets in mass quantities in proportion to reductions in the transport costs, and only in so far as at the same time the means of communication and transport themselves can yield spheres of realization for labour, driven by capital; only in so far as commercial traffic takes place in massive volume – in which more than necessary labour is replaced – only to that extent is the production of cheap means of communication and transport a condition for production based on capital, and promoted by it *for that reason.* All labour required in order to throw the finished product into circulation – it is in economic circulation only when it is present on the market – is from capital's viewpoint a barrier to be overcome – as is all labour required as a *condition* for the production process (thus e.g. expenses for the security of exchange etc.). The sea route, as the route which moves and is transformed under its own impetus, is that of trading peoples κατ᾽ ἐξοχήν. [24] On the other side, highways originally fall to the community, later for a long period to the governments, as pure deductions from production, deducted from the common surplus product of the country, but do not constitute a source of its wealth, i.e. do not cover their production costs. In the original, self-sustaining communes of Asia, on one side no need for roads; on the other side the lack of them locks them into their closed-off isolation and thus forms an essential moment of their survival without alteration (as in India). Road construction by means of the *corvée,* or through taxes, which is another form, is a forced transformation of a part of a country's surplus labour or surplus product into roads. If an individual capital is to undertake this – i.e. if it is to create the conditions of the production process which are not included in the *production* process directly – then the work must provide a profit.

Presupposing a certain road between A and B (let land cost nothing), then this contains no more than a definite quantity of labour, hence value. Whether the capitalist or the state has it built is the same thing. Does the capitalist make a gain here, then, by creating surplus labour and hence surplus value? First, strip off what is puzzling about the road, which arises from its nature as fixed capital. Imagine that the road could be sold at once, like a coat or a ton of iron. If the production of the road cost say 12 months, then its value = 12 months. If the general standard of labour is such that a worker can live from say 6 months of objectified labour, then, if he built the entire road, he would create surplus value for himself to the amount of 6 months labour; or if the commune built the road, and the worker wanted to work only the necessary time, then another worker would have to be drawn in to work 6 months. The capitalist, however, forces the one worker to work 12 months, and pays him 6. The part of the value of the road which contains his surplus labour forms the capitalist's profit. The material form in which the product appears must absolutely not interfere in laying the foundations of the theory of value through objectified labour time. But the question is precisely: can the capitalist realize the road [*den Weg verwerten*], can he realize [*realisieren*] its value through exchange? This question naturally arises with every product, but it takes a special form with the general conditions of production. Suppose the value of the road is not realized. But it is built anyway, because it is a necessary use value. How does the matter stand then? It has to be built and has to be paid for – in so far as its cost of production must be exchanged for it. It comes into existence only through a certain consumption of labour, means of labour, raw materials etc. Whether it is built by *corvée* or through taxes is the same. But it is built only because it is a necessary use value for the commune, because the commune requires it at any price. This is certainly a surplus labour which the individual must perform, whether in the form of forced labour, or in the indirect form of taxes, over and above the direct labour necessary for his subsistence. But to the extent that it is necessary for the commune, and for each individual as its *member,* what he performs is not surplus labour, but a part of his *necessary* labour, the labour necessary for him to reproduce himself as *commune member* and hence to reproduce the community, which is itself a general condition of his productive activity. If the labour time were entirely consumed in direct production (or, expressed indirectly, if it were impossible to raise surplus tax revenue for this specific purpose), then the road would have to remain unbuilt. If the whole society is regarded as one individual, then necessary labour would consist of the sum of all the particular labour functions which the division of labour separates off. This one individual would have to spend e.g. so much time for agriculture, so much for industry, so much for trade, so much for making instruments, so much, to return to our subject, for road building and means of communication. All these necessities resolve into so much labour time which must be directed towards different aims and expended in particular activities. How much labour time could be employed would depend on the amount of labour capacity (= the mass of individuals capable of labour who constitute the society) and on the development of the productive force of labour (the mass of products (use values) which it can create in a given span of time). Exchange value, which presupposes a more or less developed division of labour, depending on the level of exchange itself, presupposes that, instead of one individual (the society) doing different kinds of labour and employing his labour time in different forms, each and every individual's labour time is devoted exclusively to the necessary particular functions. If we speak of *necessary labour time,* then the particular separate branches of labour appear *as necessary.* Where exchange value is the basis, this reciprocal necessity is mediated through exchange, and shows itself precisely in the fact that every particular [piece of] objectified labour, every particularly specified and materialized [piece of] labour time exchanges for the product and symbol of labour time in general, of objectified labour time pure and simple, for money, and can thus be exchanged again for every particular labour. This necessity is itself subject to changes, because needs are produced just as are products and the different kinds of work skills. Increases and decreases do take place within the limits set by these needs and necessary labours. The greater the extent to which historic needs – needs created by production itself, social needs – needs which are themselves the offspring of social production and intercourse, are posited as *necessary,* the higher the level to which real wealth has become developed. Regarded *materially,* wealth consists only in the manifold variety of needs. The crafts themselves do not appear *necessary* ALONGSIDE self-sustaining agriculture, where spinning, weaving etc. are done as a secondary domestic occupation. But e.g. if agriculture itself rests on scientific activities – if it requires machinery, chemical fertilizer acquired through exchange, seeds from distant countries etc., and if rural, patriarchal manufacture has already vanished – which is already implied in the presupposition – then the machine-making factory, external trade, crafts etc. appear as *needs* for agriculture. Perhaps guano can be procured for it only through the export of silk goods. Then the manufacture of silk no longer appears as a luxury industry, but as a necessary industry for agriculture. It is therefore chiefly and essentially because, in this case, agriculture no longer finds the natural conditions of its own production within itself, naturally, arisen, spontaneous, and ready to hand, but these exist as an independent industry separate from it – and, with this separateness the whole complex set of interconnections in which this industry exists is drawn into the sphere of the conditions of agricultural production – it is because of this, that what previously appeared as a luxury is now necessary, and that so-called luxury needs appear e.g. as a necessity for the most naturally necessary and down-to-earth industry of all. This pulling-away of the natural ground from the foundations of every industry, and this transfer of its conditions of production outside itself, into a general context – hence the transformation of what was previously superfluous into what is necessary, as a historically created necessity – is the tendency of capital. The general foundation of all industries comes to be general exchange itself, the world market, and hence the totality of the activities, intercourse, needs etc. of which it is made up. *Luxury* is the opposite of the *naturally necessary.* Necessary needs are those of the individual himself reduced to a natural subject. The development of industry suspends this natural necessity as well as this former luxury – in bourgeois society, it is true, it does so only in *antithetical form,* in that it itself only posits another specific social standard as necessary, opposite luxury. These questions about the *system of needs* and *system of labours* – at what point is this to be dealt with? Will be seen in due course.

Now back to our road. If it can be built at all, it proves that the society possesses the labour time (living labour and objectified labour) required for its construction. [*] Why, then, as soon as production based on exchange value and division of labour appears does road building not become the business of individuals? (And it does not so become where it is conducted through taxes by the state.) First of all: the society, the united individuals, may possess the surplus time to build the road, but only in concentration. Concentration is always the addition of the part of labour capacity which each individual can employ on road building, apart from his particular work; but it is *not only* addition. The unification of their forces increases their *force of production;* but this is by no means the same as saying that all of them added together numerically would possess the same labour capacity if they did not *work together,* hence if to the sum of their labour capacities were not added the *surplus* existing only in and through their *united, combined* labour. Hence the violent rounding-up of the people in Egypt, Etruria, India etc. for forced construction and compulsory public works. Capital effects the same concentration in *another* way, through the manner of its exchange with free labour. [†] *Secondly*: On one side, the population may be developed far enough, and the support which it finds in the employment of machinery etc. may be far enough advanced on the other side, so that the power arising only from the material, *massive concentration* of labour – and in antiquity it is always this *massive* effect of forcibly concentrated labour – may be superfluous, and a *relatively* smaller *mass of living labour* may be required. [‡] A special class of road-workers may form, employed by the state, [§] or a part of the occasionally unemployed population is used for it, together with a number of superintendents etc., who do not work as capitalists, however, but as more highly educated *menials.* (About the relation of this skilled labour etc. later.) The workers are then wage workers, but the state employs them not as such, but as menial servants.

[*] It is here presupposed of course that it follows a correct instinct. It could eat up the seed grain, let the field lie fallow, and build roads. But it would thereby not have accomplished the *necessary labour,* because it would not *reproduce* itself, not maintain itself as living labour capacity through this labour. Alternatively the living labour capacities may be directly murdered, as e.g. by Peter I, to build Petersburg. This sort of thing does not belong here.

[†] That capital has to do not with isolated, individual labour but with combined labour,

just as it is in and for itself already a social, combined force, is a point which should perhaps be treated already in the general history of the rise of capital.

‡ The greater the extent to which production still rests on mere manual labour, on use of muscle power etc., in short on physical exertion by individual labourers, the more does the increase of the *productive force* consist in their collaboration *on a mass scale.* The opposite features, particularization and individualization, are displayed by the semi-artistic crafts; the skilfulness of individual, but uncombined labour. Capital, in its true development, combines mass labour with skill, but in such a way that the former loses its physical power, and the skill resides not in the worker but in the machine and in the scientific combination of both as a whole in the factory. The social spirit of labour obtains an objective existence separate from the individual workers.

§ *Among the Romans, the army constituted a mass* – but already divorced from the whole people – which was disciplined to labour, whose surplus time also belonged to the state; who sold their entire labour time for pay to the state, exchanged their entire labour capacity for a wage necessary for the maintenance of their life, just as does the worker with the capitalist. This holds for the period when the Roman army was no longer a citizen’s army but a mercenary army. This is here likewise a free sale of labour on the part of the soldier. But the state does not buy it with the production of values as aim. And thus, although the wage form may seem to occur originally in armies, this pay system is nevertheless essentially different from wage labour. There is some similarity in the fact that the state uses up the army in order to gain an increase in power and wealth.

Now, for the capitalist to undertake road building as a business, at his expense, * various conditions are required, which all amount to this, that the mode of production based on capital is already developed to its highest stage. *Firstly: Large capital* is itself presupposed, a large capital concentrated in his hands, in order that he may be able to undertake work of such dimensions and of such slow turnover, [and hence] realization. Hence mostly *share-capital,* the form in which capital has worked itself up to its final form, in which it is posited, not only *in itself,* in its substance, but is posited also in its *form,* as social power and product. *Secondly*: It must bring *interest,* but not necessarily *profit* (it may bring more than interest, but this is not required). We do not yet need to examine this point any further here. *Thirdly*: As presupposition, such a volume of traffic – commercial, above all – that the road pays for itself, i.e. that the price demanded for the use of the road *is worth* that much exchange value for the producers, or supplies a productive force for which they can pay that much. *Fourthly*: A portion of idle wealth which can lay out its revenue for these articles of locomotion. But these two presuppositions are what remains essential: (1) Capital in the required mass, employable for this object, at attractive interest; (2) it has to be worth it for the productive capitals, for industrial capital, to pay the price of passage. Thus e.g. the first railway between Liverpool and Manchester had become a necessity of production for the Liverpool cotton brokers and even more for the Manchester manufacturers. ‡ Capital as such – its being posited with the necessary scope – will produce roads only when the production of roads has become a necessity for the producers, especially for productive capital itself; a condition for the capitalist's *profit-making*. Then the road will pay for itself. But in this case, a large volume of traffic is already presupposed. It is the same presupposition *doubly*: On one side, the wealth of the country sufficiently concentrated and transformed into the form of capital, to allow it to undertake such works as realization processes for capital; on the other side the volume of traffic sufficient, and the barrier formed by the lack of means of communication sufficiently felt as such, to allow the capitalist to realize the value of the road (in instalments over time) as road (i.e. its use). All *general conditions* of *production*, such as roads, canals, etc., whether they facilitate circulation or even make it possible at all, or whether they increase the force of production (such as irrigation works etc. as in Asia and, incidentally, as still built by governments in Europe), presuppose, in order to be undertaken by capital instead of by the government which represents the community as such, the highest development of production founded on capital. The separation of *public works* from the state, and their migration into the domain of the works undertaken by capital itself, indicates the degree to which the real community has constituted itself in the form of capital. A country, e.g. the United States, may feel the need for railways in connection with production; nevertheless the direct advantage arising from them for production may be too small for the investment to appear as anything but *sunk capital.* Then capital shifts the burden on to the shoulders of the state; or, where the state traditionally still takes up a position superior to capital, it still possesses the authority and the will to force the society of capitalists to put a part of their *revenue,* not of their capital, into such generally useful works, which appear at the same time as *general* conditions of production, and hence not as *particular* conditions for one capitalist or another – and, so long as capital does not adopt the form of the joint-stock company, it always looks out only for its *particular* conditions of realization, and shifts the *communal* conditions off on to the whole country as national requirements. Capital undertakes only *advantageous* undertakings, advantageous in its sense. True, it also speculates unsoundly, and, as we shall see, *must* do so. It then undertakes *investments* which do not pay, and which pay only as soon as they have become to a certain degree *devalued.* Hence the many undertakings where the first *investment* is sunk and lost, the first entrepreneurs go bankrupt – and begin to realize themselves only at second or third hand, where the invested capital has become smaller owing to *devaluation.* Incidentally, the state itself and everything connected with it belongs with these deductions from *revenue,* belongs so to speak to the *consumption costs* for the individual, the production costs for society. A road itself may so increase the force of production that it creates new traffic which then makes the road profitable. There are works and investments which may be necessary without being productive in the capitalist sense, i.e. without the realization of the *surplus labour* contained in them through circulation, through exchange, as *surplus value.* If a worker works e.g. 12 hours per day for a year building a road, and if the generally necessary labour time is = 6 hours on the average, then he works a surplus time of 6 hours. But if the road cannot be sold for 12 hours, perhaps only for 6, then this road construction is not an undertaking for capital, and road building is not productive labour for it. Capital must be able to sell the road (the timing and mode of the sale are beside the point here) in such a way that both the necessary and the surplus labour are realized, or in such a way that it obtains out of the general fund of profits – of surplus values – a sufficiently large share to make it the same as if it had created surplus value. *This relation* is to be examined *later in connection with profit and necessary labour.* The highest development of capital exists when the general conditions of the process of social production are not paid out of *deductions from the social revenue*, the state's taxes – where revenue and not capital appears as the labour fund, and where the worker, although he is a free wage worker like any other, nevertheless stands economically in a different relation – but rather out of *capital as capital.* This shows the degree to which capital has subjugated all conditions of social production to itself, on one side; and, on the other side, hence, the extent to which social reproductive wealth has been *capitalized,* and all needs are satisfied through the exchange form; as well as the extent to which the *socially posited* needs of the individual, i.e. those which he consumes and feels not as a single individual in society, but communally with others – whose mode of consumption is social by the nature of the thing – are likewise not only consumed but also produced through exchange, individual exchange. In the case of the above road, road building must be so advantageous that the transformation of a given amount of labour time into the road must reproduce the worker's labour capacity to the same degree as if he transformed it into cultivated fields. Value is determined by objectified labour time, whatever form it may take. But it does depend now on the use value in which it is realized, whether this *value is* realizable. It is presupposed here that the road is a requirement for the commune, hence the use value is presupposed. For capital, on the other side, if it is to undertake the building of the road, it must be presupposed that not only the *necessary labour time* but also the *surplus labour time* worked by the worker can be paid for – this is where his profit comes from. (The capitalist often compels this payment by means of protective tariffs, monopoly, state coercion; while the individuals engaged in exchange, under conditions of free exchange, would *at most* pay the necessary labour.) It is very possible that surplus labour time is present but not paid for (which can after all happen to every capitalist). *Where capital rules* (just as where there is slavery and bondage or serfdom of any sort), *the worker's absolute labour time is posited for him as condition of being allowed to work the necessary labour time, i.e. of being allowed to realize the labour time necessary for the maintenance of his labour capacity in use values for himself.* Competition then has the result, in every kind of work, that he must work the full time – i.e. surplus labour time. But it may be the case that this surplus labour time, although present in the product, is not exchangeable. For the worker himself – compared with the other wage workers – it is surplus labour. For the employer, it is labour which, while it has a use value for him, like e.g. his cook, has no exchange value, hence the entire distinction between *necessary and surplus labour time* does not exist.

Labour may be necessary without being productive. All *general, communal* conditions of production – so long as their production cannot yet be accomplished by capital as such and under its conditions – are therefore paid for out of a part of the country's revenue – out of the government's treasury – and the workers do not appear as productive workers, even though they increase the productive force of capital.

* If the state lets this sort of matter be conducted through *state-contractors,* then this still always takes place indirectly through the *corvée* or taxes.

† *Competition* is better suited to create the necessity of e.g. the railway in a country where the previous development of its forces of production would not yet push so far. The effect of *competition among nations* belongs in the section on *international intercourse.* The civilizing influences of capital particularly show themselves here.

The result of our digression is, incidentally, that the production of the means of communication, of the physical conditions of circulation, is put into the category of the production of fixed capital, and hence does not constitute a special case. Meanwhile, and incidentally, there opened up for us the prospect, which cannot be sharply defined yet at this point, *of a specific relation of capital to the communal, general conditions of social production,* as distinct from the conditions of a *particular capital* and its *particular production* process.

Transport to market (spatial condition of circulation) belongs in the production process. Credit, the temporal moment of circulation. – Capital is circulating capital. – Money circulation a mere illusion. – Sismondi. Cherbuliez. (Capital. Its various component parts)

Circulation proceeds in space and time. Economically considered, the spatial condition, the bringing of the product to the market, belongs to the production process itself. The product is really finished only when it is on the market. The movement through which it gets there belongs still with the cost of making it. It does not form a necessary moment of circulation, regarded as a particular value-process, since a product may be bought and even consumed at the point of its production. But this spatial moment is important in so far as the expansion of the market and the exchangeability of the product are connected with it. The reduction of the costs of this *real* circulation (in space) belongs to the development of the forces of production by capital, the reduction of the costs of its realization. In certain respects, as an external condition for the existence of the economic process of circulation, this moment may also be reckoned as part of the *production costs* of circulation, so that, with respect to this moment, circulation itself appears as a moment not only of the production process in general, but also of the direct production process. In any case, what appears here is the determination of this moment by the general degree of development of the productive forces, and of production based on capital generally. This locational moment – the bringing of the product to market, which is a necessary condition of its circulation, except when the point of production is itself a market – could more precisely be regarded as the transformation of the product *into a commodity.* Only on the market is it a *commodity.* (Whether or not this forms a particular moment is a matter of chance. If capital produces to order, then neither this moment nor the transformation into money exists as a particular moment for it. *Work done to order,* i.e. supply corresponding to a prior demand, as a *general or predominant situation,* is not characteristic of large industry and in no way arises from the nature of capital as a condition.)

Secondly, the temporal moment. This is an essential part of the concept of circulation. Suppose the act of making the transition from commodity to money is fixed by contract, then this still requires time – calculating, weighing, measuring. The abbreviation of this moment is likewise development of productive force. However, this is time still conceived only as an *external* condition for the transition from the state of money into that of commodity; the transition itself is presupposed; the question is the time which *elapses during this presupposed act.* This belongs to the *cost of production.* Quite different is the time which generally passes before the commodity makes its transition into money; or the time during which it remains a *commodity,* only a potential but not a real value. This is pure loss.

It is clear from everything said above that circulation appears as an essential process of capital. The production process cannot be begun anew before the transformation of the commodity into money. The *constant continuity* of the process, the unobstructed and fluid transition of value from one form into the other, or from one phase of the process into the next, appears as a fundamental condition for production based on capital to a much greater degree than for all earlier forms of production. On another side, while the necessity of this continuity is given, its phases are separate in time and space, and appear as particular, mutually indifferent processes. It thus appears as a matter of chance for production based on capital whether or not its essential condition, the continuity of the different processes which constitute its process as a whole, is actually brought about. The suspension of this chance element by capital itself is *credit.* (It has other aspects as well; but this aspect arises out of the direct nature of the production process and is hence the foundation of the necessity of credit.) Which is why *credit* in any developed form appears in no earlier mode of production. There was borrowing and lending in earlier situations as well, and usury is even the oldest of the antediluvian forms of capital. But borrowing and lending no more constitute *credit* than working constitutes *industrial labour* or *free wage labour.* And credit as an essential, developed relation of production appears *historically* only in circulation based on capital or on wage labour. *(Money* itself is a form for suspending the unevenness of the times required in different branches of production, to the extent that this obstructs exchange.) Although *usury* is itself a form of credit in its *bourgeoisified* form, the form *adapted to capital,* in its pre-bourgeois form it is rather the *expression of lack of credit.*

(The retransformation of money into objective moments or conditions of production presupposes the latters' *availability.* It constitutes the various *markets* where the producer encounters them as commodity – in the hands of a merchant – markets which (alongside the labour market) are essentially distinct from the markets for direct, individual, final consumption.)

Money became transformed into commodity through circulation, and in the exchange of M–C, consumption completed the process; or, the commodity was exchanged for money – and in the exchange C–M, M was either a vanishing moment itself to be exchanged for C again, in which case the process ended with consumption again, or the money withdrew from circulation and transformed itself into dead treasure, merely symbolic wealth. At no point did the process ignite from within, but rather the presuppositions of money circulation lay outside it, and it constantly required a new push from the outside. In so far as both moments were exchanged, their change of form within circulation was merely formal. But in so far as content entered in, it dropped out of the economic process; content did not form a part of it. The commodity did not sustain itself as money, nor the money as commodity; each was either one or the other. Value as such did not sustain itself in and through circulation as predominant over the process of its transformation, its metamorphosis; nor was the *use value* itself (as is the case in the capital production process) produced by the *exchange value.* With capital the consumption of the commodity is itself not final; it falls within the production process; it itself appears as a moment of production, i.e. of *value-positing* [*Wertsetzen*].

Capital is now posited, however, as not merely sustaining itself formally, but as *realizing itself as value,* as value relating to itself as value in every one of the moments of its metamorphosis, in which it appears at one time as money, at another time as commodity, then again as exchange value, then again as use value. The passage from one moment to the other appears as a particular process, but each of these processes is the transition to the other. Capital is thus posited as value-in-process, which is capital in every moment. [25] It is thus posited as *circulating capital;* in every moment capital, and circulating from one form into the next. The point of return is at the same time the point of departure and vice versa – namely the *capitalist.* All capital is originally circulating capital, product of circulation, as well as producing circulation, tracing in this way its own course. From the present standpoint, money circulation now appears as itself merely a moment of the circulation of capital, and its independence is posited as a mere *semblance.* It appears as determined on all sides by the circulation of capital, to which we shall return. In so far as it forms an independent motion alongside that of capital, this independence is posited only by the *continuity* of the circulation of capital, so that this one moment may be held constant and regarded for itself.

<'Capital a permanent, *self-multiplying* value which never decays. This *value* tears itself loose from the commodity which created it; remains, like a *metaphysical, insubstantial quality,* always in the possession of the same farmer,' (e.g.), 'for whom it cloaks itself in different forms.' (Sism. VI.) [26] 'In

the exchange of labour for capital, the worker demands subsistence *in order to live;* the capitalist demands *work in order to make a profit.'* (Sism. loc. cit.) 'The master of the workshop gains, makes a profit from every *increase in the powers of production* which the *division of labour* brings about.' (loc. cit.) [27] 'Sale of labour = renunciation of all fruits of labour.' (Cherbuliez, ch. XXVIII.) [28] 'The three component parts of capital do not grow evenly' (i.e. *matière première,* instrument, *approvisionnement*), [29] 'nor are they in the *same relation* in the different stages of society. The *approvisionnement* remains the same for a certain period, regardless of how quickly the *speed of production* and consequently the *quantity of products* may increase. Thus an increase of *productive capital* does not necessarily entail an increase of the *approvisionnement* which is destined to form the price of labour; it can be accompanied by a reduction of it.' (loc. cit.) [30]>

Influence of circulation on the determination of value. – Circulation time = time of devaluation. – Difference between the capitalist mode of production and all earlier ones (universality etc.). Propagandistic nature of capital. – Abbreviation of circulation (credit). – Storch. – What the capitalist advances is labour. (Malthus.) – Barriers to capitalist production. (Thompson) [31]

<In as much as the renewal of production depends on the sale of the finished products; transformation of the commodity into money and retransformation of money into the conditions of production – raw material, instrument, wages; in as much as the circuits which capital travels in order to go from one of these forms into the other constitute sections of circulation, and these sections are travelled in specific *amounts of time* (even spatial distance reduces itself to time; the important thing e.g. is not the market's distance in space, but the speed – the amount of time – with which it can be reached), by that much the velocity of circulation, the *time* in which it is accomplished, is a determinant of how many products can be produced in a given period of time; how often capital can be realized in a given period of time, how often it can *reproduce* and *multiply* its value. Thus a moment enters *into value-determination* which

indeed does not come out of the direct relation of labour to capital. The frequency with which the same capital can repeat the production process (creation of new value) in a given period of time is evidently a condition not posited directly by the production process itself. Thus, while circulation does not itself produce a moment of *value-determination,* for that lies exclusively in labour, its speed does determine the speed with which the production process is repeated, values are created – thus, if not *values,* at least to a certain extent the mass of values. Namely, the values and surplus values posited by the production process, multiplied by the number of repetitions of the production process in a given period of time. When we speak of the velocity of the circulation of capital, we postulate that delays in the transition from one phase to the next arise only from *external barriers,* not such as arise from the production process and circulation itself (such as crises, overproduction etc.). Thus, in addition to the labour time realized in production, the *circulation time* of capital enters in as a moment of value creation – of productive labour time itself. While labour time appears as value-positing activity, this circulation time of capital appears as the *time of devaluation.* The difference shows itself simply in this: if the totality of the labour time commanded by capital is set at its maximum, say infinity, ∞, so that necessary labour time forms an infinitely small part and surplus labour time an infinitely large part of this [infinity], then this would be the maximum realization of capital, and this is the tendency towards which it strives. On the other side, if the *circulation time of capital* were = 0, if the various stages of its transformation proceeded as rapidly in reality as in the mind, then that [32] would likewise be the maximum of the factor by which the production process could be repeated, i.e. the number of capital realization processes in a given period of time. The repetition of the production process would be restricted only by the amount of time which it lasts, the amount of time which elapses during the transformation of raw material into product. *Circulation time* is therefore not a positive value-creating element; if it were = to 0, then value-creation would be at its maximum. But if either surplus labour time or necessary labour time = 0, i.e. if necessary labour time absorbed all time, or if production could proceed altogether *without* labour, then neither value, nor capital, nor value-creation would exist. *Circulation time* therefore determines value only in so far as it appears as a *natural barrier* to the realization of labour time. It is therefore in fact a deduction from *surplus labour time,* i.e. an increase of *necessary labour time.* It is clear that necessary labour time has to be paid for, whether the circulation process proceeds slowly or quickly. E.g. in trades where specific workers are required, who can, however, only be employed for a part of the year because the products are, say, saleable only in a given season, [in those trades] the workers would have to be paid for the entire year, i.e. surplus labour time is decreased in exact proportion to the reduction in their possibilities of employment during a given period of time, but still they must be paid in one way or another. (For example in the form that their wages for 4 months suffice to maintain them for a year.) If capital could utilize them for 12 months, it would pay them no higher, and would have gained that much surplus labour. *Circulation time thus appears as a barrier to the productivity of labour* = an increase in necessary labour time = a decrease in surplus labour time = a decrease in surplus value = an obstruction, a barrier to the self-realization process [*Selbstverwertungsprozess*] of capital. Thus, while capital must on one side strive to tear down every spatial barrier to intercourse, i.e. to exchange, and conquer the whole earth for its market, it strives on the other side to annihilate this space with time, i.e. to reduce to a minimum the time spent in motion from one place to another. The more developed the capital, therefore, the more extensive the market over which it circulates, which forms the spatial orbit of its circulation, the more does it strive simultaneously for an even greater extension of the market and for greater annihilation of space by time. (If labour time is regarded not as the working day of the individual worker, but as the indefinite working day of an indefinite number of workers, then all *relations of population* come in here; the basic doctrines of population are therefore just as much contained in this first chapter on capital as are those of profit, price, credit etc.) There appears here the universalizing tendency of capital, which distinguishes it from all previous stages of production. Although limited by its very nature, it strives towards the universal development of the forces of production, and thus becomes the presupposition of a new mode of production, which is founded not on the development of the forces of production for the purpose of reproducing or at most expanding a given condition, but where the free, unobstructed, progressive and universal development of the forces of production is itself the presupposition of society and hence of its reproduction; where advance beyond the point of departure is the only presupposition. This tendency – which capital possesses, but which at the same time, since capital is a limited form of production, contradicts it and hence drives it towards dissolution – distinguishes capital from all earlier modes of production, and at the same time contains this element, that capital is posited as a mere point of transition. All previous forms of society – or, what is the same, of the forces of social production – foundered on the development of wealth. Those thinkers of antiquity who were possessed of consciousness therefore directly denounced wealth as the dissolution of the community. The feudal system, for its part, foundered on urban industry, trade, modern agriculture (even as a result of individual inventions like gunpowder and the printing press). With the development of wealth – and hence also new powers and expanded intercourse on the part of individuals – the economic conditions on which the community rested were dissolved, along with the political relations of the various constituents of the community which corresponded to those conditions: religion, in which it was viewed in idealized form (and both [religion and political relations] rested in turn on a given relation to nature, into which all productive force resolves itself); the character, outlook etc. of the individuals. The *development of science alone* – i.e. the most solid form of wealth, both its product and its producer – was sufficient to dissolve these communities. But the *development of science,* this ideal and at the same time practical wealth, is only one aspect, one form in which the *development of the human productive forces,* i.e. of wealth, appears. Considered *ideally,* the dissolution of a given form of consciousness sufficed to kill a whole epoch. In reality, this barrier to consciousness corresponds to a *definite degree of development of the forces of material production* and hence of wealth. True, there was not only a development on the old basis, but also a *development of this basis itself.* The highest development of this *basis* itself (the flower into which it transforms itself; but it is always *this* basis, *this* plant as flower; hence wilting *after* the flowering and as consequence of the flowering) is the point at which it is itself worked out, developed, into the form in which it is compatible with the *highest development of the forces of production,* hence also the richest development of the individuals. As soon as this point is reached, the further development appears as decay, and the new development begins from a new basis. We saw earlier that property in the conditions of production was posited as identical with a limited, definite form of the community; hence of the individual with the characteristics – limited characteristics and limited development of his productive forces – required to form such a community. This presupposition was itself in turn the result of a limited historic stage of the development of the productive forces; of wealth as well as of the mode of creating it. The purpose of the community, of the individual – as well as the condition of production – [is] *the reproduction of these specific conditions of production* and of the individuals, both singly and in their social groupings and relations – as living carriers of these conditions. Capital posits the *production of wealth* itself and hence the universal development of the productive forces, the constant overthrow of its prevailing presuppositions, as the presupposition of its reproduction. Value excludes no use value; i.e. includes no particular kind of consumption etc., of intercourse etc. as absolute condition; and likewise every degree of the development of the social forces of production, of intercourse, of knowledge etc. appears to it only as a barrier which it strives to overpower. Its own presupposition – value – is posited as product, not as a loftier presupposition hovering over production. The barrier to *capital* is that this entire development proceeds in a contradictory way, and that the working-out of the productive forces, of general wealth etc., knowledge etc., appears in such a way that the working individual *alienates* himself [*sich entäussert*]; relates to the conditions brought out of him by his labour as those not of his *own* but of an *alien wealth* and of his own poverty. But this antithetical form is itself fleeting, and produces the real conditions of its own suspension. The result is: the tendentially and potentially general development of the forces of production – of wealth as such – as a basis; likewise, the universality of intercourse, hence the world market as a basis. The basis as the possibility of the universal development of the individual, and the real development of the individuals from this basis as a constant suspension of its *barrier,* which is recognized as a barrier, not taken for a *sacred limit.* Not an ideal or imagined universality of the individual, but the universality of his real and ideal relations. Hence also the grasping of his own history as a *process,* and the recognition of nature (equally present as practical power over nature) as his real body. The process of development itself posited and known as the presupposition of the same. [33] For this, however, necessary above all that the full development of the forces of production has become the *condition of production;* and not that specific *conditions of production* are posited as a limit to the development of the productive forces. –

If we now return to the *circulation time* of capital, then its abbreviation (except for development of the means of communication and transport required to bring the product to market) [means] in part the *creation* of a continuous and hence an ever more extensive market; and in part the development of *economic* relations, development of forms of capital, by means of which it *artificially* abbreviates the circulation time. *(All forms of credit.)* <It may be further remarked at this point that, since capital alone possesses the conditions of the production of capital, hence satisfies and strives to realize [them], [it is] a general tendency of capital at all points which are presuppositions of circulation, which form its productive centres, to assimilate these points into itself, i.e. to transform them into capitalizing production or production of capital. This propagandistic (civilizing) tendency a property exclusively of capital – as distinct from the earlier conditions of production.> The modes of production where circulation does not form the immanent, dominant condition of production, naturally [do] not [meet] the specific circulation requirements of capital and hence also do not [provide for] the working-out of the economic forms as well as of the real forces of production corresponding to them. – Production based on capital originally came out of circulation; we now see that it posits circulation as its own condition, and likewise the production process in its immediacy as moment of the circulation process, as well as the circulation process as one phase of the production process in its totality. – In so far as different capitals have different circulation times (e.g. one a more distant market, the other a near one; one a guaranteed transformation into money, the other a risky one; one more fixed capital, the other more circulating capital), this makes for differences among them in realization. But this happens only in the secondary realization process. Circulation time in itself is a *barrier* to realization (*necessary labour time* is of course also a barrier; but at the same time an element, since value and capital would vanish without it); [it is a]

deduction from surplus labour time or an increase in *necessary labour time* in relation to *surplus labour time.* The circulation of capital *realizes value,* while living labour *creates value.* Circulation time is only a barrier to this realization of value, and, to that extent, to value creation; a barrier arising not from production generally but specific to production of capital, the suspension of which – or the struggle against which – hence also belongs to the specific economic development of capital and gives the impulse for the development of its forms in credit etc. <Capital itself is the contradiction [, in] that, while it constantly tries to suspend *necessary labour time* (and this is at the same time the reduction of the worker to a minimum, i.e. his existence as mere living labour capacity), *surplus labour time* exists only in antithesis with necessary labour time, so that capital posits necessary labour time as a *necessary* condition of its reproduction and realization. At a certain point, a development of the forces of material production – which is at the same time a development of the forces of the working class – *suspends capital itself.*>

<'The entrepreneur can resume production only after he has sold the completed product, and has employed the price for the purchase of new materials and wages: thus, the more prompt circulation is in bringing about these two effects, the more is he capable of beginning his production anew, and the more products does the capital supply in a given period of time.' (Storch, 34.) [34]> <'The specific *advances of the capitalist* do not consist of cloth etc., but of labour.' (Malthus, IX, 26.) [35]> <'The accumulation of the general capital of the community in other hands [than] those of the operative labourers, necessarily retards the progress of all industry save that of the usual remuneration of capital, which the time and circumstances afford to the holders of the capital ... In the previous systems, the *force of production regarded in reference to and subordinate to actual accumulations,* and to the perpetuating of the existing modes of distribution. Actual accumulation and distribution are subordinate to the power of producing.' (Thompson, 3.) [36]>

Circulation and creation of value. (Equalization between different capitals in the conditions of circulation.) Capital not a source of value-creation. – Circulation costs. – Continuity of production presupposes suspension of circulation time

It follows from the relation of circulation time to the production process that the sum of values produced, or the total realization of capital in a given epoch, is determined not simply by the new value which it creates in the production process, or by the surplus time realized in the production process, but rather by this surplus time (surplus value) multiplied by the number which expresses how often the production process of capital can be repeated within a given period of time. The number which expresses this frequency of repetition may be regarded as the coefficient of the production process or of the surplus value created through it. However, this coefficient is not positively but negatively determined by the velocity of circulation. I.e. if the velocity of circulation were absolute, i.e. if no interruption in production resulting from circulation occurred at all, then this coefficient would be at its maximum. If the real conditions of e.g. wheat production in a given country permit only one harvest, then no velocity of circulation can make two harvests out of it. But if an obstruction in the circulation occurred, if the farmer could not sell his wheat soon enough e.g. to hire workers again, then production would be delayed. The maximum of the coefficient of the production process or the realization process in a given period of time is determined by the absolute time taken up by the production phase itself. With circulation completed, capital is able to begin its production process anew. Thus if circulation caused no delay at all, if its velocity were absolute and its duration = 0, i.e. if it were accomplished in no time, then this would only be the same as if *capital* had been able to begin its production process anew directly it was finished; i.e. circulation would not have existed as a limiting barrier for production, and the repetition of the production process in a given period of time would be absolutely dependent on, identical with, the duration of the production process. Thus if the development of industry allowed x lb. of twist to be produced in 4 months with a capital of 100, then with that capital the production process could be repeated only 3 times per year, and only $3x$ lb. of twist could be produced. No velocity of circulation could increase the reproduction of capital, or rather the repetition of its realization process, beyond that point. That could occur only in consequence of an *increase in the forces of production.* Circulation time in itself is not a *productive force* of capital, but a *barrier to its productive force* arising from its nature as exchange value. The passage through the various phases of circulation here appears as a *barrier to production,* a barrier posited by the specific nature of capital itself. All that can happen through the acceleration and abbreviation of *circulation time* – of the circulation process – is the reduction of the barrier posited by the nature of capital. The natural barriers to the repetition of the production process e.g. in agriculture coincide with the duration of one cycle of the production phase. The barrier posited by capital is the lag not between seeding and harvest, but between harvest and the transformation of the harvest into money, and retransformation of the money into say e.g. purchase of labour. The circulation-artists who imagine that they can do something with the velocity of circulation other than lessen the obstacles to reproduction posited by capital itself are on the wrong track. (Even madder, of course, are those circulation-artists who imagine that credit institutes and inventions which abolish the lag of circulation time will not only do away with the delays and interruptions in production caused by the transformation of the finished product into capital, but will also make the capital, with which productive capital exchanges, itself superfluous; i.e. they want to produce on the basis of exchange value but to remove at the same time, by some witchcraft, the necessary conditions of production on this basis.) The most that credit can do in this respect – as regards *mere* circulation – is maintain the continuity of the production process, *if* all other conditions of this continuity are present, i.e. if the capital to be exchanged with actually exists etc.

It is posited in the circulation process that the transformation of the capital into money is posited as a condition for the realization of capital through production, for the exploitation of labour by capital; or, the exchange of capital for capital * is posited as barrier to the exchange of capital for labour and vice versa.

* For from the present standpoint we still only have labour or capital at all points of circulation.

Capital exists as capital only in so far as it passes through the phases of circulation, the various moments of its transformation, in order to be able to begin the production process anew, and these phases are themselves phases of its realization – but at the same time, as we saw, of its *devaluation.* As long as capital remains frozen in the form of the finished product, it cannot be active as capital, it is *negated* capital. Its realization process is delayed in the same degree, and its value-in-process [*prozessierender Wert*] negated. This thus appears as a loss for capital, as a relative loss of its value, for its value consists precisely in its realization process. This loss of capital means in other words nothing else but that time passes it by unseized, time during which it could have been appropriating alien labour, *surplus labour time* through exchange with living labour, if the deadlock had not occurred. Now let us imagine *many* capitals in particular branches of business, all of which are *necessary* (which would become evident if, in the eventuality of a massive flight of capital from a given branch, supply falling below demand, the market price would therefore rise above the natural price in that branch), and let a single branch of business require e.g. that capital A remain longer in the form of devaluation, i.e. that the time in which it passes through the various phases of circulation is longer than in all other branches of business, in which case this capital A would regard the smaller new value which it could produce as a positive loss, just as if it had so many more outlays to make in order to produce the same value. It would thus charge relatively more exchange value for its products than the other capitals, in order to share the same rate of gain. But this could take place in fact only if the loss were distributed among the other capitals. If A demands more exchange value for the product than there is labour objectified in it, then it can obtain this *more* only if the others obtain less than the real value of their products. That is, the less favourable conditions under which A has produced would be borne in proportional shares by all the capitalists who exchange with it, and in this way an equal average level would come out. But the sum of the surplus value created by all these capitals together would be lessened exactly by the amount of capital A's lesser realization in relation to the other capitals; only, instead of this reduction falling exclusively on capital A, it is borne as a general loss, as a loss shared proportionally by all the capitals. Nothing can therefore be more ridiculous than the notion (see e.g. Ramsay) [37] that, apart from the exploitation of labour, capital forms an *original* source, separately from labour, of *value-creation,* because the distribution of surplus labour among the capitals takes place not in proportion to the surplus labour time achieved by the individual capital, but in proportion to the *total surplus labour* which the totality of capitals achieved, and hence a higher value-creation can be attributed to the *individual capital* than is directly explicable from its *particular* exploitation of labour power. But this *more* on one side has to be compensated by a *less* on the other. This is what *average* means, if it means anything at all. The question how the relation of capital to alien capital, i.e. the competition of capitals, distributes the surplus value among them obviously has nothing to do with the absolute amount of this surplus value. Nothing more absurd, then, than to conclude that, because one capital obtains a compensation for its *exceptional* circulation time, i.e. puts its relatively lesser realization to account as positively greater realization, now all *capitals* combined, *capital* can make something out of nothing, make a plus out of a minus, make a plus-surplus value out of a minus-surplus value or out of minus-surplus labour time, and that it possesses, therefore, a *mystical* wellspring of value independent of the appropriation of alien labour. The manner in which the capitals among other things compute their proportional share of the *surplus value* – not only according to the surplus labour time which they set in motion, but also *in accordance with the time which their capital has worked as such,* i.e. lain fallow, found itself in the phase of devaluation – does of course not alter in the least the total sum of the surplus value which they have to distribute among themselves. This sum itself cannot grow by being smaller than it would have been if capital A, instead of lying fallow, had created surplus value; i.e. by having created less surplus value in the same time as the other capitalists. And this *lying-fallow* is made good for capital A only in so far as it arises necessarily out of the conditions of the particular branch of production, and hence appears in respect to *capital as such* as a burden on realization, as a *necessary barrier* to its realization generally. The division of labour leaves this barrier as a barrier only as regards the production process of this particular capital. If the production process is regarded as conducted by capital as such, this lying-fallow is a *general barrier* to capital's realization. If one imagines all production carried out by labour alone, then all the larger advances which it requires during its realization appear as what they are – *deductions from surplus value.*

Circulation can *create value* only in so far as it requires fresh employment – of *alien labour* – in addition to that directly consumed in the production process. This is then the same as if more *necessary labour* were used in the direct production process. Only the actual *circulation costs* increase the *value* of the product, but decrease the surplus value.

To the extent that the circulation of capital (the product etc.) does not merely express the phases necessary to begin the production process anew, this circulation (see Storch's example) does not form a moment of production in its totality – is hence not circulation posited by production, and, in so far as it creates expenses, these are *faux frais de production.* [38] The costs of circulation generally, in so far as their merely economic moments, circulation proper, are concerned (bringing the product to market gives it a *new use value),* are to be regarded as deduction from *surplus value,* i.e. as an increase of necessary labour in relation to surplus labour.

The continuity of production presupposes that circulation time has been suspended. If it has not been suspended, then time must pass between the different metamorphoses through which capital must travel; its circulation time *must* appear as deduction from its production time. On the other hand, the nature of capital presupposes that it travels through the different phases of circulation not as it does in the mind, where one concept turns into the next at the speed of thought, in no time, but rather as situations which are separate in time. It must spend some time as a cocoon before it can take off as a butterfly. Thus the conditions of production arising out of the nature of capital itself contradict each other. The contradiction can be suspended and overcome only * in two ways:

Firstly, credit: A pseudo-buyer B – i.e. someone who really *pays* but does not really buy – mediates the transformation of capitalist A's product into money. But B himself is paid only after capitalist C has bought A's product. Whether the money which this credit-man, B, gives to A is used by A to buy labour or to buy raw material and instrument, before A can replace either of them from the sale of his product, does not alter the case. Given our presupposition, he must basically give him both – i.e. all the conditions of production (these represent, however, a greater value than the original ones with which A began the production process). In this case capital B replaces capital A; but they are not realized at the same time. Now B takes the place of A; i.e. his capital lies fallow, until it is exchanged with capital C. It is frozen in the product of A, who has made his product liquid in capital B.

[*] Except if one imagines that all capitals produce to order for each other, and that the product is therefore always immediately money, a notion which contradicts the nature of capital and hence also the practice of large-scale industry.

Ramsay. Circulation time. Concludes therefore that capital is its own source of profit. – Ramsay. Confusion about surplus value and profit and law of values. (No surplus value according to Ricardo's law.) – Ricardo. Competition. – Quincey. [39] *Ricardo's theory of value. Wages and profit.* **Quincey. – Ricardo. – Wakefield.** *Conditions of capitalist production [in] colonies*

The economists' absolute confusion in respect of Ricardo's determination of value through labour time – something which is founded on a basic defect of his own development – emerges very clearly with Mr Ramsay. He says (after having previously drawn, from the influence of the circulation time of capitals on their *relative realization,* i.e. their relative share of the general surplus value, the nonsensical conclusion that: 'This shows how capital may regulate value independently of labour' (IX, 84. R, 43) [40] or 'that capital is a source of value independent of labour' [41]) – he says, literally: 'A circulating capital *(approvisionnement)* will always maintain more labour than that formerly bestowed upon itself. Because, could it employ no more than had been previously bestowed upon itself, *what advantage* could arise to the owner from the use of it *as such?'* (loc. cit. 49.) 'Given two capitals of equal value, each produced through the labour of 100 men operating for a given time, of which the one is entirely circulating, the other entirely fixed, and may perhaps consist of wine kept to improve. Now, this circulating capital, *raised by the labour of 100 men, will set 150 men in motion.* Therefore the product at the end of the coming year will in this case be the result of the labour of 150 men. But still it will be of no more value than the wine at the termination of the same period, although only 100 men employed upon the latter.' (50.) 'Or is it asserted that the quantity of labour which every circulating capital *will employ* is no more than equal to the [quantity] previously bestowed upon it? That would mean, that the *value of the capital expended* = that of the product.' (52.) Great confusion between the labour bestowed upon capital and that which it will employ. The capital which is exchanged for labour capacity, the *approvisionnement* – and this he here calls *circulating capital* – can never employ more labour than has been bestowed upon it. (The reaction of a development of the productive forces on present capital is beside the point here.) But there has been more labour bestowed upon it than it has paid for – *surplus labour,* which is converted into *surplus value and surplus produce,* enabling the capital to renew this profitable bargain, where the mutuality is all on one side, on a more enlarged scale. It is enabled to employ more new living labour, because during the process of production a portion of fresh labour has been bestowed upon it beyond the accumulated labour of which it consisted before entering that process.

Mr Ramsay seems to imagine that, if a capital is the product of 20 working days (necessary and surplus together), this product of 20 working days can employ 30 working days. But this is by no means the case. Say that 10 days of necessary labour and 10 surplus days were employed on the product. Then the surplus value = 10 surplus days. If the capitalist then exchanges these again for raw material, instrument and labour, then he can set new *necessary labour* into motion with the *surplus product.* The point is not that he employed more labour time than is present in the product, but that he exchanges the surplus labour time, which costs him nothing, for new necessary labour time – in other words, precisely, that he employs the *entire labour time* bestowed upon the product, while he has paid only part of that labour. Mr Ramsay's conclusion, that if the quantity of labour which every circulating capital will employ was no more than equal to that previously bestowed upon it, the value of the capital expended would be equal to that of the produce, i.e. no surplus value would be left, would be correct only if the quantity of labour bestowed upon the capital *were wholly paid for,* i.e. if capital did not appropriate a part of the labour *without equivalent.* These misunderstandings on Ricardo's part [42] obviously arise from the fact that he himself was not clear about the process, nor, as a bourgeois, could he be. Insight into this process is = to the statement that capital is not only, as A. Smith thinks, [43] command over alien labour, in the sense that every exchange value is that, since it gives its possessor *buying power,* but that it is the power to appropriate alien labour *without exchange, without equivalent,* but with the semblance of exchange. Ricardo knows no argument to refute those, like A. Smith and others, who fall into the same error regarding value as determined by labour, and value as determined by the price of labour (wages), other than to say: with the product of the same quantity of labour one can set sometimes more and sometimes less living labour into motion, i.e. he regards the product of labour in respect of the worker only as *use value* – only the part of the product which he needs to be able to live as worker. But how it comes about that the worker suddenly only represents *use value* in the exchange, or only draws use value from the exchange, is by no means clear to him, as is already proved by his arguments against A. Smith, which are never in general terms, but always about particular examples. But why is it, then, that the share of the worker in the value of the product is determined not by the value, but rather by the use value of the product, thus not by the labour time employed on it, but by its quality of maintaining living labour capacity? If he tries to explain this with, say, competition among the workers, then the answer which would have to be given is the same as that which he gives A. Smith about competition among capitalists, i.e. that competition may well even out, equalize the level of profit, but in no way creates the measure of this level. [44] Likewise, competition among the workers could press down a higher wages level etc., but the general standard of wages, or as Ricardo puts it the natural price of wages, could not be explained by the competition between worker and worker, but only by the original relation between capital and labour. Competition generally, this essential locomotive force of the bourgeois economy, does not establish its laws, but is rather their executor. Unlimited competition is therefore not the presupposition for the truth of the economic laws, but rather the consequence – the form of appearance in which their necessity realizes itself. For the economists to presuppose, as does Ricardo, that unlimited competition exists [45] is to presuppose the full reality and realization of the bourgeois relations of production in their specific and distinct character. Competition therefore does not *explain* these laws; rather, it lets them be *seen,* but does not produce them. Then Ricardo says, too: the production costs of living labour depend on the production costs of making the values required to reproduce it. [46] While he previously regarded the product in relation to the worker only as a use value, he now regards the worker only as an *exchange value* in relation to the product. The historic process through which product and living labour come into this mutual relation is none of his concern. He is just as vague about the way in which this relation is perpetuated. Capital, with him, is the *result of saving;* this already shows that he misunderstands the process of its origins and reproduction. He therefore also imagines that production is impossible without capital, although he can very well imagine capital possible without ground rent. The distinction between *profit* and *surplus value* does not exist for him, proof that he is clear about the nature of neither one. His procedure already shows this from the very beginning. Originally, he makes workers exchange with workers – and their exchange is then determined by the equivalent, by the labour time reciprocally expended in production. Then comes the real problem of his economics, to demonstrate that this determination of value is not altered by the accumulation of capitals – i.e. by the presence [*Dasein*] of capital. Firstly, he has no inkling that his first spontaneous relation is itself only a relation abstracted from the mode of production resting on capital. Secondly, what he has available is a *definite amount of objective labour time,* which may of course increase, and he asks himself, how is it *distributed?* The question is rather how is it created, and there it is precisely the specific nature of the relation of capital and labour, or the specific and distinct character of capital, which explains this. As Quincey (X, 5) puts it, modern economics (the economics of Ricardo) is in fact concerned only with the dividends, while the total product is regarded as fixed, determined by the quantity of labour employed on it – its value appraised in accordance with that. [47] Accordingly, Ricardo has rightly been accused of not understanding *surplus value,* although his opponents understand it even less. Capital is represented as appropriating a certain part of the ready and available value of labour (of the product); the creation of this value, which it appropriates above and beyond the reproduced capital, is not presented as the *source* of the surplus value. This creation is identical with the appropriation of alien labour *without exchange,* and for that reason the bourgeois economists are never permitted to understand it clearly. Ramsay accuses Ricardo of forgetting that the fixed capital (which consists of capital not included in *approvisionnement,* with Ramsay the *raw material* at the same time along with the *instrument*) is a deduction from the sum total available for distribution among capitalist and worker. 'Ricardo forgets that the whole product is divided not only between wages and profits, but that another part is necessary for replacing fixed capital.' (IX, p. 88. R. 174, note.) Indeed, since Ricardo does not grasp the relation between objectified and living labour in its living movement – [a relation] not to be deduced from the dividends of a given quantity of labour, but from the positing of surplus labour – and does not, therefore, grasp the relation among the different component parts of capital, it therefore seems with him as if the entire product were divided into wages and profits, so that the reproduction of capital is itself counted as part of profit. Quincey (loc. cit. Notebook X, 5) gives this exposition of the Ricardian doctrine: 'If the price is 10s. then wages and profit as a whole cannot exceed 10s. But do not the wages and profits as a whole, themselves, on the contrary, predetermine the price? No, that is the old superannuated doctrine.' (p. 204). 'The new economics has shown that all price is governed by *proportional quantity of the producing labour,* and by that only. Being itself once settled, then ipso facto, *price settles the fund* out of which both wages and profits must derive their *separate dividends.'* (loc. cit. 204.) [48] Capital here appears not as positing surplus value, i.e. surplus labour, but only as making deductions from a given quantity of labour. The fact that instrument and raw material appropriate these *dividends* then has to be explained by their *use value* in production, which then presupposes the absurdity that raw material and instrument create use value through their *separation* from labour. For this *separation* makes them into capital. Considered for themselves, they are themselves labour, accumulated labour. Besides, this clashes with sound common sense, because the capitalist knows very well that he counts wages and profit among the production costs and regulates the *necessary price* accordingly. This contradiction in the determination of the product by relative labour time, and the limitation of the sum of profit and wages by the sum of this labour time, and the *real determination of prices* in practice, comes about only because profit is not grasped as itself a derivative, secondary form of *surplus value;* the same is true of what the capitalist justly regards as *his production costs.* His profit arises simply from the fact that a part of the cost of production costs him nothing, hence does not enter into *his* outlays, *his* production costs.

NOTEBOOK VI

February 1858

The Chapter on Capital (continuation)

‘Any change that can disturb the existing relations between wages and profits must originate in wages.’ (Quincey. loc. cit. (X, 5) p. 205.) This is true only in so far as any variations in the mass of surplus labour must be derived from a variation in the relation between necessary and surplus labour. But this can likewise come about if necessary labour becomes less productive and hence a greater part of the total labour falls to it, or if the total labour becomes more productive, hence necessary labour time is reduced. It is nonsense to say that this productive force of labour arises from *wages.* The relative reduction of wages is rather its result. But it arises (1) from the appropriation by capital of the growth in the productive forces resulting from division of labour, trade which brings cheaper raw materials, science etc.; (2) but this increase of the productive forces has to be regarded as being initiated by capital in so far as it is realized through the employment of a greater capital etc. Further: profit and wages, although determined by the relation of necessary and surplus labour, do not coincide with it, are only secondary forms of the same. The point, however, is this: the Ricardians presuppose a definite quantity of labour; this determines the price of the product, out of which labour, in wages, and capital, in profits, then draw their dividends; the workers’ dividend = the price of the necessaries of life. Hence in the ‘existing relations between wages and profits’, the rate of profit is at its maximum and that of wages at its minimum. Competition among capitals can change only the relation in which they share the total profit, but cannot alter the relation between total profit and total wages. The general standard of profit is this relation of the total profit to the total wages, and this is not altered through competition. Hence, where does the alteration come from? Certainly not because the profit rate voluntarily declines, and it would have to do so voluntarily since competition does not have this result. Hence it is due to an alteration in wages, whose necessary costs may rise (theory of the progressive deterioration of the soil in agriculture; theory of rent) in consequence of a decrease in the productive force of labour due to natural causes. Carey etc. replies, correctly, to this (but, in the way he explains it, incorrectly again) that the rate of profit falls, as a result not of a decrease but rather of an increase in the productive force. [1] The solution of the whole matter is simply that the rate of profit is not the same as the absolute surplus value, but is rather the surplus value in relation to the capital employed, and that the growth of productive force is accompanied by the decrease of that part of capital which represents *approvisionnement* in relation to that part which represents invariable capital; hence, when the relation between total labour and the capital which employs it falls, then the part of labour which appears as surplus labour or surplus value necessarily falls too. This inability to explain one of the most striking phenomena of modern production is the source of Ricardo's failure to understand his own principle. But the difficulties in which he thereby entangles his disciples may be seen in this quotation among others from Quincey: 'It is the common paralogism, that if upon the same farm you have always kept 5 men, and in 1800 their produce was 25 qrs, but in 1845 50 qrs, you are apt to view the *produce only as variable,* and the *labour as constant:* whereas *virtually* both have varied. In 1800 each qr must have cost 1/5 part of a man; in 1845 each has cost no more than 1/10 part of a man.' (loc. cit. 214.) In both cases the absolute labour time was the same, 2 days; but in 1845 the productive force of labour had doubled in comparison with 1800, and therefore the cost of producing necessary labour was less. The labour bestowed upon 1 quarter was less, but the total labour was the same. Mr Quincey should, however, have learned from Ricardo that the productive force of labour does not determine the value of the product – although it determines the surplus value, albeit not in step with the increase of the productive force. These arguments *against* Ricardo, as well as the desperate sophistries of his disciples (e.g. Mr MacCulloch, who cites surplus labour as the source of the surplus value of old wine compared with new wine). [2] Nor is value to be determined by the labour which the unit cost, i.e. the *price* of the single quarter. *Rather, the price multiplied by the number constitutes the value.* The 50 quarters in 1845 had *the same value* as the 25 in 1800, because they objectified the same amount of labour. The price of each single quarter, the unit, *must* have been different, and the *total price* (expressed in money) may have been different, for very different reasons. (What Quincey says about the machine holds for the worker: 'A machine, as soon as its secret is known, will not sell for the labour produced, but for the labour producing … it will no longer be viewed as a *cause equal to certain effects,* but *as an effect certainly reproducible* by a known cause *at a known cost.'* (84.) De Quincey says about Malthus: 'Malthus in his Political Economy refuses to see, nay he positively denies, that if two men produce a variable result of ten and five, then in one case each unit of the result has cost double the labour which it has cost in the other. On the contrary, because there are always two men, Mr Malthus obstinately insists that the *cost in labour* is constant.' (loc. cit. 215, note.) In fact: *the cost in labour is constant,* because, by presupposition, just as much labour is contained in ten as in five. But the *cost of labour* is not constant, because in the first case, where the productive force of labour [is] double, the time belonging to necessary labour [is] in a certain proportion less. We shall go into Malthus's view immediately after this. Here, before we go further in the development of the circulation time of capital and its relation to labour time, it is proper first to examine Ricardo's whole doctrine about this matter, in order to establish the difference between our own conception and his more sharply. (The quotations from Ricardo in Notebook VIII.) [3]

First presupposition with him, *'competition without restriction',* and unhampered increase of products through industry. (19. R. 5.) [4] This means in other words nothing other than that the laws of capital are completely realized only within *unlimited competition* and *industrial production.* Capital develops adequately on the latter productive basis and in the former relation of production; i.e. its immanent laws enter completely into reality. Since this is so, it would have to be shown how this *unlimited competition* and *industrial production* are conditions of the realization of capital, conditions which it must itself little by little produce (instead of the hypothesis appearing here as merely that of the theoretician, who places free competition and the productive mode of capital's existence externally and arbitrarily into the relation of capital to itself as capital, not as developments of capital itself, but as imaginary presuppositions of capital for the sake of purity.) This by the way the only place in Ricardo where a faint notion of the *historic* nature of the laws of bourgeois economy. With this presupposition, the *relative value* of commodities (this word meaningless, since absolute value is nonsense) is determined by the different quantity which can be produced in the same labour time, or by the quantity of labour relatively realized in different commodities. (p. 4.) (Notebook, 19.) (Henceforth the first number for the page in the notebook; the second for the page in Ricardo.) [5] Now, how one gets from value as equivalent determined by labour to the non-equivalent, i.e. to the value which posits surplus value through exchange, i.e. how one gets from value to capital, from one aspect to its apparent opposite, this does not interest Ricardo. The only question for him: how the *value relation* between the commodities can remain the same and can and must be determined by relative quantities of labour, *although* the owners of accumulated labour ... do not exchange labour *equivalents* in living labour, i.e. despite the relation of capital and labour. It is then a very simple arithmetical proof that commodity A and commodity B can exchange in relation to the labour realized in them, although the producers of A or B *distribute* product A, or the product B exchanged for it, in different ways among themselves. But since all *distribution* here proceeds on the basis of exchange, it appears in fact altogether impossible to explain why one of the exchange values – living labour – is exchanged according to the amount of labour time realized in it, while the other exchange value – accumulated labour, capital – is not exchanged according to the standard of the labour time realized in it. Bray e.g. therefore believes that he is the first to draw the true conclusion from Ricardo with his equal exchange between living and dead labour. [6] That from the standpoint of exchange alone, the *worker's pay* would have to = *the value of the product,* i.e. the amount of labour in objective form which the worker obtains in pay, = the amount of labour in subjective form which he expends in labour, is so necessary a conclusion that A. Smith falls into it. [7] Ricardo, by contrast, avoids this fallacy, but how? 'The *value* of labour, and the quantity of commodities which a specific quantity of labour can buy, are not identical.' Why not? *'Because* the worker's product or an equivalent of this product is not = to the worker's pay.' I.e. the identity does not exist, *because* a difference exists. 'Therefore' (because this is not the case) 'it is not the value of labour which is the measure of value, but the quantity of labour bestowed on the commodity.' (19, 3.) [8] Value of labour is not identical with wages of labour. *Because* they are different. *Therefore* they are not identical. This is a strange logic. There is basically no reason for this other than that it is *not* so in practice. But it ought to be so, according to the theory. For the exchange of values [is] determined by the labour time realized in them. Hence equivalents are exchanged. Thus a specific quantity of labour time in living form would have to exchange for the same quantity of labour time in accumulated form. What would have to be demonstrated is precisely that the law of exchange turns into its precise opposite. Not even a faint suspicion that it does so is expressed here. Or the suspicion would have to lie in the frequently repeated admonition against mixing them up; that the distinction between past and living labour cannot do the job either is readily admitted: 'The comparative quantity of commodities which a given quantity of labour will produce determines their past and present value' (19, 9) where living labour thus even determines the value of past labour retroactively. Why then is capital not also exchanged for living labour in proportion to the labour realized in the capital? Why is it that a quantity of living labour is not itself = the quantity of labour in which it has objectified itself? 'Labour is by nature of different quality, and it is difficult to compare different hours of labour in different branches of business. But this scale is very soon established in practice.' (19, 13.) 'For short periods, at least from year to year, the variation in this inequality is insignificant, and is *therefore* left out of account.' (19, I 5.) This is nothing. If Ricardo had applied his own principle, the amounts of (simple) labour to which the different *labour capacities* are reducible, then the matter would have been simple. Generally, he is concerned straight away with the hours of labour. What the capitalist acquires through exchange is *labour capacity:* this is the exchange value which he pays for. Living labour is the use value which this exchange value has for him, and out of this use value springs the surplus value and the suspension of exchange as such. Because Ricardo allows exchange with living labour – and thus falls straight into the production process – it remains an insoluble antinomy in his system that a certain quantity of living labour does not = the commodity which it creates, in which it objectifies itself, although the value of the commodity = to the amount of labour contained in it. The value of the commodity 'includes also the labour of bringing the commodity to market'. (19, 18.) We shall see that circulation time, in so far as it appears as determining value with Ricardo, is only the labour required to bring the commodities to market. 'The principle of value-determination by the relative amounts of labour contained in the commodity is considerably modified by the employment of machinery and other fixed and durable capital. A rise or fall in wages differently affects two capitals of which one is almost entirely circulating, the other almost entirely fixed; likewise the unequal duration of the fixed capital employed. Namely, there is added the *profit on fixed capital* (interest), as well as the compensation for the greater length of time which must elapse before the more valuable of the two commodities can be brought to market.' (19, 29, 30.) The latter moment concerns only the duration of the production process, i.e. labour time directly employed, at least in Ricardo's example of the farmer and the baker. (If one farmer's wheat becomes ready for the market later than another's, then this so-called *compensation* already presupposes *interest;* thus already something derivative, not an original aspect.)

'Profit and wages are only *portions* in which the two classes, of capitalists and workers, partake in the original commodity, i.e. also in that exchanged for it.' (p. 31.) The very great extent to which the production of *the original commodity,* its origin, is itself determined by these *portions,* the extent to which, therefore, it *precedes* these portions as basic determinant, proves that the *original commodity* [would] not be produced at all, if it did not contain surplus labour for capital. 'Commodities on which the same quantity of labour has been bestowed vary in relative value if they cannot be brought to market in the same amount of time. With a *greater fixed capital,* too, the higher value of a commodity is due to the greater length of time which must elapse before it can be brought to market … The difference arises in both cases from the profits being accumulated as capital, and is only a compensation for the *time during which profits were withheld.'* (34, 35.) This means absolutely nothing other than that capital lying fallow is *reckoned in and up* as if it were not lying fallow, but were being exchanged with surplus labour time. This has nothing to do with the determination of value. It belongs with price. (In the case of fixed capital it [enters] into the determination of value only as *another method* of paying for the objectified labour, abstracted from the profit.)

'There is another principle of labour which nothing points out to the economic inquirer in old countries, but of which every colonial capitalist has been made conscious in his own person. By far the greater part of the operations of industry, and especially those of which the *produce is great in proportion to the capital and labour employed,* require *a considerable time for* [*their*] *completion.* As to most of them, it is not worth while to make a commencement without the certainty of being able to carry them on for several years. A large portion of the capital employed in them is *fixed, inconvertible, durable.* If anything happens to stop the operation, all this capital is lost. *If the harvest cannot be gathered, the whole outlay in making it grow* has been thrown away ... This shows that *constancy* is a no less important principle than combination of labour. The importance of the principle of constancy is not seen here, because rarely indeed does it happen, that the labour which carries on a business, is stopped against the will of the capitalists ... But in the *colonies* just the opposite. Here capitalists are so much afraid of it that they avoid its occurrence as much as they can, by avoiding, as much as possible, operations which require much time for their completion.' (Wakefield, 169, XIV, 71.) [9] 'There are numerous *operations of so simple a kind* as not to admit a *division into parts,* which cannot be performed without the cooperation of many pairs of hands. For example, the lifting of a large tree on to a wain, keeping down weeds in a large field of growing crops, shearing a large flock of sheep at the same time, gathering a harvest of corn at the time when it is ripe enough and not too ripe, moving any great weight; everything, in short, which cannot be done unless a good many pairs of hands help together in the same undivided employment, and at the same time.' (168 loc. cit.) '*Combination and constancy of labour* are provided for in old countries, without an effort or thought on the part of the capitalist, merely by the *abundance of labourers for hire.* The scarcity of labourers for hire is the universal complaint of colonies.'(170 loc. cit.) 'Only the *cheapest land* in a colony is that whose price affects the *labour market. The price of this land, as of all bare land, and of everything else which it costs nothing to produce,* depends of course on the *relation between the demand and supply.'* (p. 332.) ... 'In order that *the price of waste land* should accomplish its objects' (namely of making the worker into a non-landowner), 'it must be *sufficient* for the purpose. Hitherto the price has been everywhere insufficient.' (338 loc. cit.) This 'sufficient' price: 'In founding a colony the price might be so low as to render the quantity of land appropriated by settlers practically unlimited: it might be high enough to occasion a proportion between land and people similar to that of old countries, in which case, if this very high price did not prevent emigration, the cheapest land in the colony might be as dear, and the superabundance of labourers as deplorable as in England: or it might be a just medium between the two, occasioning neither superabundance of people nor superabundance of land, but so limiting the quantity of land as to give the cheapest land a market value that would have the effect of compelling labourers to work some considerable time for wages before they could become landowners.’ (339 loc. cit.) (Notebook XIV, 71.) (These excerpts here quoted from Wakefield’s *Art of Colonization* belong with the ones given above about the necessary separation of the worker from the conditions of property.)

Surplus value and profit. **Example** ***(Malthus). – Profit and surplus value.*** **Malthus** ***– Difference between labour and labour capacity. – The peculiar assertion that the introduction of capital in no way changes the payment of labour. – Carey’s theory of the cheapening of capital for the worker. – (Decline of the profit rate.) – Wakefield on the contradiction between Ricardo’s theories of wage labour and of value***

(The calculation of profit as distinct from the calculation of the real surplus value which capital posits in the exchange with living labour, made clear e.g. in the following example. It is a statement in the *first Report of the Factory Commissioners.* (Malthus’s *Princip. of Polit. Economy,* 1836, 2nd ed. (Notebook X, p. 42).)

Capital sunk in building and machinery	£10,000
Floating capital	£7,000

£500	interest on £10,000 fixed capital
350	floating capital
150	Rents, taxes, rates
650	Sinking fund of 6 1/2% for wear and tear of the fixed capital
£1,650	
£1,100	Contingencies, carriage, coal, oil
2,750	
2,600	Wages and salaries

5,350
10,000 for about 400,000 lb. raw cotton at 6d.

15,350
16,000 for 363,000 lb. twist spun. Value £16,000

The capital laid out in labour is 2,600; the surplus value = 1,650 (850 interest + 150 rents etc., makes 1,000 + 650 profit).

But 2,000:1,650 = 100:63 6/13. Thus the rate of surplus value is 63 6/13%. According to the profit calculation it would have to be 850 interest, 150 rents and 650 profit, or 1,650:15,350; nearly 10.1%.

In the above example, the floating capital turns over 167/70 times per year; the fixed capital turns over once in 15 5/13 years; once in 200/13 year.

Profit: 650 or about 4.2. [10] The wages of the operatives 1/6. The profit is indicated here as 4.2; say it were only 4%. This 4% figured on an outlay of 15,350. But then we also have 5% interest on £10,000 and 5% on 7,000; £850 = 5% of 17,000. From the actual annual advances made, we must deduct (1) the part of the fixed capital which does not figure in the sinking fund; (2) that which is figured as interest. (It is possible that capitalist A does not pocket the interest, but capitalist B. In any case they are revenue, not capital; surplus value.) From the £15,350 outlays thus deduct 850; leaves: £14,500. Of the £2,600 for wages and salaries there were £183 1/3 in the form of salary, since 1/6 of 14,500 is not 2,600 but 2,416 2/3, and 14,500 divided by this is 6.

Thus, he sells the 14,500 at 16,000 or a profit of 1,500; makes 10 2/3%; but let us ignore these 2/3 and say 10%; 1/6 of 100 is 16 2/3. Thus, out of 100, he would give: 83 1/3 for advances, 16 2/3 wages and 10 profit. In detail:

	Advances	*Wages*	*Sum*	*Reproduces*	*Profit*
£ St.:	83 1/3	16 2/3	100	110	10

10 of 16 2/3 or of 50/3 is exactly 60%. Thus, in order that, in the capitalist’s calculation, an annual profit of 10% (it was slightly more) be made on a capital of £17,000, wherein labour makes up only 1/6 of the annual advances of 14,500, the worker (or capital, as you like) has to create a surplus value of 60%. Or, of

the total labour time 40% are for necessary and 60 for surplus labour; they relate as 4:6 or = 2:3 or 1:3/2. If, however, the advances on capital had been 50, the advances on wages also 50, then only 20% surplus value would have to be created in order that the capitalist should have 10%; 50 50 10 = 110. But 10 to 50 = 20:100 or 20%. If necessary labour in the second case posited as much surplus labour as in the first, then the capitalist's profit would amount to £30; on the other hand if the rate of real value-creation, the positing of surplus labour, in the first case, were only as great as in the second, then the profit would amount to only £3 1/3, and if the capitalist had to pay 5% interest to another capitalist, then he would have to carry an actual loss. This much arises simply from the formula, (1) that, in order to determine the size of the real surplus value, one must calculate the profit on the advance made for wages; the percentage which expresses the proportion between the so-called profit and wages; (2) the relatively smaller percentage made up by the proportion between the outlay in living labour and the total outlay presupposes a greater outlay in fixed capital, machinery etc.; greater division of labour. Thus, although the percentage of labour is smaller than in the capital working with more labour, the mass of labour really set in motion must be significantly greater; i.e. a greater capital generally has to be worked with. The proportional part of labour out of the total advance is smaller; but the absolute sum of labour set in motion is larger for the individual capital; i.e. it must itself be larger. (3) If it is a case not of larger machinery etc., but of an instrument which does not set more labour into motion and itself represents no greater fixed capital (e.g. manual lithography) but merely replaces labour, then the profit of the capital working with the machine is absolutely smaller than that of the capital working with living labour. (But the latter can make a percentage profit higher than the former, and thus throw him out of the market.) (etc.) The examination of how far the rate of profit can decrease as capital grows, while the gross profit nevertheless increases, belongs to the doctrine of profit *(competition).*

In his *Principles of Political Economy,* 2nd ed., 1836, Malthus has an inkling that profit, i.e. not profit, but *real surplus value,* has to be calculated not in respect of capital advanced, but of living labour advanced, whose value is expressed objectively in wages; but this leads him into playing games which become absurd if they are to serve as a basis for any determination of value, or for reasoning about the relation of labour to the determination of value.

For example, if I take the total value of the finished product, then I can compare every part of the product advanced with the part of the outlay corresponding to it; and the percentage of profit in relation to the whole product is naturally the same percentage for any fractional part of the product. Say e.g. that 100 thalers brought 110; thus 10% the whole product; 75%, say, for the invariable part of capital, 25 for labour, i.e. 3/4 for the former, 1/4 for living labour. Now if I take 1/4 of the total product, i.e. of 110, then I obtain 27 2/4 or 27 1/2. On an outlay of 25 for labour, the capitalist would have a gain of 2 1/2, i.e. 10%. Likewise Malthus could have said that if I take 3/4 of the total product, i.e. 75, then these 3/4 are represented in the total product by 82 1/2; then 7 1/2 out of 75 is exactly 10%. This obviously means nothing other than that if I gain 10% on 100 then the gain on every part of 100 amounts to as much as, when added together, will be 10% on the total sum. If I have gained 10 on 100, then on 2 × 50 I have gained 5 each time etc. The fact that, if I gain 10 on 100, I gain 2 1/2 on 1/4 of 100 and 7 1/2 on 3/4 takes us not a single step further. If I have gained 10 on 100, how much have I then won on 1/4 of 100 or on 3/4? Malthus's insight can be reduced to this childishness. The advance for labour amounted to 1/4 of the 100, and the gain on it amounted to 10%. 10% of 25 is 2 1/2. Or the capitalist, if he has gained 10 on 100, has gained 1/10 on every part of his capital, i.e. 10%. This gives the parts of the capital no qualitative character whatever, and it therefore holds for fixed capital etc. just as well as for the part advanced in labour. Moreover, this only expresses the illusion that each part of the capital is involved to an equal degree in the newly created value. Nor has the 1/4 of the capital advanced for wages created the surplus value; rather, the unpaid living labour has done so. However, from the relation of the total value – here the 10 thalers – to wages we can see what percentage of labour was not paid, or, how much surplus labour there was. In the above relation, the necessary labour is objectified in 25 thalers, the surplus labour in 10; thus they relate as 25:10 = 100:40; 40% of the labour was surplus labour, or, what is the same, 40% of the value it produced was surplus value. It is quite true that the capitalist can make this reckoning: if I make 10 on 100, then, on wages, = 25, I have made 2 1/2. It is impossible to see what use this calculation is. But what Malthus wants to do with it will be seen shortly when we go into his determination of value. However, it is clear from the following that he indeed believes that his simple arithmetical example contains a real determination:

‘Suppose the capital be expended only for wages, £100 expended in immediate labour. The returns at the end of the year 110, 120, or 130; it is evident that in each case the profits will be determined by the proportion of the *value of the whole produce* which is required to pay the labour employed. If the value of the produce in the market = 110, the proportion required to pay the labourers = 10/11 of the value of the produce, or the profits = 10%.’ (Here Mr Malthus does nothing more than to express the original advance, £100, as a relation to the total product. 100 is 10/11 of 110. Whether I say I gain 10 on 100, i.e. 1/10 of 100, or I say 1/11 of the 110 are gain, it is the same.) ‘If the value of the product is 120, the proportion for labour = 10/12 and the gain 20%; if 130, the proportion required to pay the labour = 10/13 and the gain = 30%.’ (Instead of saying: I gain 10 on 100, I can also say that 10/11 of the 110 were the advances; or, 20 on the 100, the advances amount only to 10/12 of 120 etc. The character of these advances, whether in labour or otherwise, has absolutely nothing to do with this other arithmetic form of expressing the matter. If a capital of 100 has brought in 110, then either I can start with the capital and say I gained 10 on it, or I can start with the product, with 110, and say that I advanced only 10/11 on it beforehand. The relation is, of course, the same.) ‘Now assume that the capitalist’s advances do not consist entirely of labour. The capitalist *expects an equal benefit on all parts of the capital he advances’* (that means simply that he distributes the benefit he has made, and whose origin may be quite obscure to him, among all parts of his outlays equally, entirely abstracting away their qualitative difference). ‘Suppose 1/4 of the advances, for labour’ (direct), ‘3/4 consisting of accumulated labour and profits, with any additions which may arise of rents, taxes and other outgoings. *Then strictly true that the profits of the capitalist will vary with the varying value of this 1/4 of the produce compared with the quantity of labour employed.’* (Not quantity with Mr Malthus, but rather compared with the salary paid.) (Thus strictly true that his profits will vary with the varying value of the 3/4 of his profits compared with the advances in accumulated labour, i.e. the gain relates to the total capital advanced (10:100) as every part of the total product (110) does to the part of the advance corresponding to it.) ‘For example,’ Malthus continues, ‘a farmer employs £2,000 in cultivation, of which 1,500 in seed, keep of horses, wear and tear of his fixed capital, etc., and £500 on immediate labour, and the returns at the end are 2,400. His profit 400, on 2,000 = 20%. And it is immediately obvious that if we took 1/4 of the value of the produce, namely £600, and compared it with the amount paid in the wages of the immediate labour, the result would show exactly the same rate of profits.’ (loc. cit. 267, 268. Notebook X, 41, 42.) (It is equally obvious that if we took 3/4 of the value of the produce, namely 1,800, and compared it with the amount paid in the advances on accumulated labour, namely with 1,500, the result would show exactly the same rate of profits. 1,800:1,500 = 18:15 = 6:5. And 6 is 1/5 more than 5, hence 20%.) (Malthus here has two different arithmetic formulae in mind and gets them mixed up: *firstly,* if I make 10 on 100, then on every part of the 100 my gain is not 10 but 10%: i.e. 5 on 50, 2 1/2 on 25 etc.; to gain 10 on 100 means to gain 1/10 on each part of the 100, and consequently the profit has to show up also as 1/10 profit on wages, and if the profit is distributed evenly among all parts of the capital, then I can say that the rate of profit on the total capital varies with the rate of profit on each of its parts, including e.g. the part advanced as wages; *secondly* if I gained 10% on 100, then the total product 110. Now, if wages formed 1/4 of the advances = 25, then they form only a 4 2/5 part of 110; i.e. they form a fraction that is smaller by 2/5, and it will form an ever smaller part of the total product in proportion as the latter has risen in comparison with the original. This is again only another way of calculating. 10 is 1/10 of 100 but only 1/11 of 110. I can therefore say that as the total product grows larger, each of the fractional parts of the original capital forms a relatively smaller part of it. Tautology.)

In his work *The Measure of Value Stated and Illustrated,* London, 1823 (Notebook IX), Malthus asserts that the *‘value of labour’* is *‘constant’* and is hence the true Measure of Value generally. ‘Any given quantity of labour must be of the *same value* as the wages which command it, or for which it actually exchanges.’ (p. 5, loc. cit.) (IX, 29.) He is speaking here, of course, about wage labour. The truth is rather: any given quantity of labour is = the same quantity of labour expressed in a product; or, each product is only a specific quantity of labour, objectified in the value of the product, which is measured with respect to other products by this quantity. Wages, however, express the value of living labour capacity, but in no way the *value* of living labour, which is expressed, rather, in wages + profit. Wages are the price of *necessary labour.* If the worker had to work 6 hours in order to live, and if he produced for himself as mere worker, then he would daily receive the commodity of 6 hours of labour, say 6d. Now the capitalist makes him work 12 hours, and pays him 6d. He pays him 1/2d. per hour, i.e. a given quantity of 12 hours of labour has the value of 12d., and 12d. is indeed the value for which the product exchanges, when it gets sold. On the other hand, the capitalist commands with this value, if he could re-invest it in mere labour, 24 hours. The wages command, therefore, a much greater quantity of labour than they consist of, and a given quantity of living labour actually exchanges for a much smaller one of accumulated labour. The only thing that is sure is that the price of labour, wages, must always express the quantity of labour which the labourers want in order to keep soul and body together. The wages of any quantity of labour must be equal to the quantity of labour which the labourer must expend upon his own reproduction. In the above instance a man would set to work two men for 12 hours each – together 24 hours – with the quantity of labour afforded by one man. In the case above, the product would be exchanged for another product with a value of 12d., or for 12 hours of labour, and this would be the source of its profit of 6d. (its surplus value for the capitalist). The value of products is determined by the labour contained in them, not by that part of the labour in them which the employer pays for. *The value of the product is constituted by labour done, including that not paid for;* but wages *only* express *paid labour,* never all labour *done.* The measure of this payment itself depends on the productivity of labour, for the latter determines the amount of necessary labour time. And since these wages constitute the *value of labour* (labour itself posited as commodity), this value is constantly variable, and is the opposite of constant. The amount of labour which the worker works is very different from the amount of labour that is worked up into his labour capacity, or which is required to reproduce his labour capacity. But he does not sell as commodity the use made of him, he sells himself not as cause but as effect. Let us listen how Mr Malthus exerts himself to get the matter clear:

'The conditions of the supply of commodities do not require that they should retain always the same relative values, but that each should retain its proper *natural* value, or the means of obtaining those objects which will continue to the producer *the same power of production* AND accumulation … profits are calculated upon the advances necessary to production … *the specific advances of capitalists do not consist of cloth, but of labour;* AND *as no other object whatever can represent a given quantity of labour,* it is clear that it is the *quantity of labour which a commodity will command,* and not the quantity of any other commodity, which can represent the condition of its supply, or its *natural value.'* (17, 18.) (IX, 29.) Already, from the fact that the capitalist's *advances* consist of *labour,* Malthus could have seen that the matter has not become clear. Posit that the necessary labour time is 6 hours; also A, B, two men each of whom works for himself but who exchange with one another. Let A work 6 hours, B 12 hours. Now if A wants to eat up the 6 extra hours worked by B, if he wants to consume the product of B's 6 surplus hours, there is nothing he can give him other than 6 hours of living labour, say the next day. B now has a product of 6 hours of labour more than A. Now posit that under these circumstances he begins to fancy himself a capitalist and stops working altogether. Then on the third day, the only thing he could give in exchange for A's 6 hours is his own accumulated product of 6 hours, and, as soon as this exchange was accomplished, he would have to begin working again himself, or starve. But if he continues to work 12 hours for A, and A continues to work 6 hours for himself and 6 for B, then they exchange exactly 12 hours with one another. The *natural value* of the commodity, says Malthus, consists in its giving back to its possessor through exchange *the same power of production* AND *accumulation.* His commodity consists of 2 quantities of labour, one quantity of accumulated labour + one quantity of immediate labour. Thus if he exchanges his commodity for another which contains exactly the same total quantity of labour, then his power of production and accumulation has remained at least the same, equal. But it grew, because a part of the immediate labour has cost him *nothing,* while he sells it nevertheless. Yet Malthus comes to the conclusion that the quantity of labour of which the product consists is paid labour *only,* hence = to the sum of the wages, or, that *wages* are the measuring rod of the value of the commodity. If every amount of labour contained in the commodity were paid for, then Mr Malthus's doctrine would be correct, but it would be equally true that his capitalist would have no 'advances of labour' to make, and his 'powers of accumulation would become totally forfeited'. Where is the profit to come from, if no unpaid labour is performed? Well, thinks Mr Malthus, [from] the wages for accumulated labour. But since labour *done* has ceased to work, it also ceases to draw wages. True, the product in which it exists could now be again exchanged for living labour, but posit that this product = 6 hours of labour; then the worker would give 6 hours of living labour and would receive the advances, the capitalist's 6 hours of done labour, in return; so that the capitalist would not have budged a single step forward. Living labour would very soon be in possession of his dead labour. The reason Malthus gives, however, is that because 'no other object whatsoever can represent a given quantity of labour', the natural value of a commodity consists of 'the quantity of labour which a commodity will command, and not the quantity of any other commodity'. That means a given quantity of labour can be represented only by a quantity of living (immediate) labour. Not 'no other object whatsoever' but rather 'every object whatsoever' can represent a given quantity of labour, namely every object in which the same quantity of labour is contained. But Malthus wants the quantity of labour contained in the commodity to be measured by, to be equal to, not the *quantity of living labour* which it can set in motion, but the *quantity of paid labour* which it sets in motion. Posit that the commodity contains 24 hours of labour; he thinks, then, that the capitalist can buy 2 working days with it; and if the capitalist paid all of this labour, or if the quantity of labour done = the quantity of paid living labour, then he could buy *only* 24 hours of living labour with his 24 hours of done labour, and his 'powers of accumulation' would have gone to the wall. But the capitalist does not pay the worker the labour time, the amount of labour, but rather pays him only the necessary labour, while forcing him to work the rest free of charge. Thus, with the 24 hours of done labour he may perhaps set 48 hours of living labour into motion. Thus he in fact pays 1 hour of done labour for 2 hours of living labour, and thus gains 100% on the exchange. The value of his commodity now = 48 hours, but is in no way equal to the wages exchanged for them, nor equal to the wages for which it then in turn exchanges. If he continues in the same way, his 48 hours of done labour will buy 96 hours of living labour.

Posit that no capitalists exist at all, but that the independent and mutually exchanging workers worked more than necessary to live, because they want to accumulate too, etc. Call that part of the work which the worker does in order to live, *wages;* and the surplus time he works in order to accumulate, *profit.* Then the value of his commodity would be = to the total amount of labour contained in it, = to the total sum of living labour time; but in no way = to the wages he paid himself, or equal to the part of the commodity which he would have to reproduce in order to live. Because the value of a commodity = a specific quantity of labour, Malthus says it is = to the quantity of necessary labour (i.e. wages) contained in it, and not = to the total sum of labour contained in it; its totality is = to a fraction of it. But the worker's 'powers of accumulation' evidently would arise only because he has worked more than necessary to pay himself his wages. If a specific quantity of living labour time were = to the time required for the worker to live, then a specific quantity of living labour would be = to the wages which he produces, or the wages would be exactly equal to the living labour which they set in motion. If such were the case, capital would of course be impossible. If the worker, in the whole of his working time, can produce not a farthing more than his wages, then with the best of wills he cannot squeeze out a farthing for the capitalist. Property is the offspring of the productivity of labour. 'If one can produce only for one, everyone a worker; there can be no property. If one man's labour can maintain 5, there will be 4 idle men for 1 employed in production.' (Ravenstone.) [11] We saw above how Malthus's fantasizing profundity expressed itself in a purely childish kind of calculation. What lay behind this, by the way, was the doctrine that the value of labour was constant and that wages constituted price. Because the rate of profit on a total capital can be expressed as the same rate on the fraction of the capital made up by wages, he asserts that this fractional part constitutes and determines the price. Exactly the same *profundity* as here. If commodity A = an amount of x commodity, he thinks that this can mean nothing else than that it = x living labour, for only labour can represent labour. From this he concludes that commodity A = the amount of *wage labour* which it can command, and that therefore the value of labour is constant, because always = to the commodity by which it is set in motion. The nub of it is simply that the amount of living labour and the amount of wage labour are identical for him, and that he believes that every fractional part of wage labour is really paid for. But x living labour can be (and, as wage labour, always is) = $x - y$ necessary labour (wages) + y surplus labour. x dead labour can therefore set in motion $x - y$ necessary labour (wages) + y surplus labour time; i.e. it always sets in motion as many additional hours of living labour time as there are hours of surplus labour time over and above necessary labour time contained within x hours of labour.

Wage labour always consists of paid and unpaid labour.

The value of labour is constant, thus means nothing other than that all labour time is necessary, i.e. wage-producing labour time. There is no surplus labour time but – nevertheless – there are ‘powers of accumulation’ and capital. Since wages are always equal to a given quantity of labour, namely the quantity of living labour which they set in motion, and since this is the same quantity of labour contained in the wages, therefore the *value of labour* is constant, for it is always = to the quantity of objectified labour. The rise and fall in the price of commodities, not of the *value of labour.* If a worker gets 8s. silver per week or 16, this comes about only because the price of shillings has risen or fallen, but the value of labour has remained the same. In both cases he obtains a week of done labour for a week of living labour. Mr M. proves this as follows:

‘If labour alone, without capital, were employed in procuring the fruits of the earth, the greater facility of procuring one sort of them compared with another would not, it is acknowledged, alter the value of labour, or the exchangeable value of the whole produce obtained by a given quantity of exertion.’ [12]

This means nothing but that each of the commodities, regardless of their quantity, would be determined by the labour contained in it, despite the fact that, depending on the degree of its productivity, it would express itself in one case in more, in another in fewer, use values. ‘*We should, without hesitation, allow that the difference was in the cheapness or dearness of the produce, not of the labour.’* [13] We would say labour is more productive in one branch than in the other, or, alternatively, the product costs more or less labour. We could not speak of cheapness or dearness of labour, since no *wage labour* existed, and hence an hour of immediate labour would always command an hour of objectified labour, which would naturally not prevent one hour from being more productive than another. But still, to the extent that we distinguish the part of labour necessary for subsistence from the part that is surplus labour – and if any hours of the day are at all worked as surplus time, then it is the same as if every fractional part of labour time consisted of a part necessary and a part surplus labour – done by the immediate labourers, it could still not be said that the *value of labour,* i.e. *wages* (the part of the product exchanged for necessary labour, or the part of the total labour which is employed for the necessary product), are *constant.* The fractional part of labour time which reproduces wages would vary with productivity; thus, with the productivity of labour, the *value of labour,* i.e. wages, would constantly vary. Wages would be measured both before and after by a definite *use value,* and since the latter constantly varies in its exchange value depending on the productivity of labour, wages would change, or [in other words] the *value of labour. Value of labour* presupposes in principle that living labour is *not* equal to its product, or, what is the same, that it is sold not as an acting cause, but as itself a produced effect. 'The value of labour is constant' means nothing further than that it is constantly measured by the quantity of labour contained in it. A product may contain more or less labour. Therefore sometimes a greater, sometimes a lesser portion of product A may exchange for product B. But the quantity of living labour which the product buys can never be greater or smaller than the done labour which it represents, for a given quantity of labour is always a given quantity of labour, whether it exists in the form of objectified or in the form of living labour. Thus if more or less of a product is given for a specific quantity of living labour, i.e. if wages rise and fall, then this comes about not because the value of labour rose or fell, for the value of a specific quantity of labour is always equal to the same specific quantity of labour, but rather because the products have cost more or less labour, because a greater or lesser quantity of the products thus represents the same quantity of labour. *Thus the value of labour remains constant. Only the value of the products changes,* i.e. the productivity of labour changes, not its values. This is the pith of the theory of Malthus, if you can call such a shallow fallacy a theory. First of all, a product which has cost only half a working day may suffice for me to live and work a whole day. Whether or not the product possesses this quality depends not on its *value,* i.e. the labour time bestowed on it, but rather on its *use value,* and the exchange which takes place in this regard between living labour and the product of labour is not an exchange between both as use values, but rather their relation lies on the one side in the use value of the product, on the other side in the conditions of the existence of living labour capacity. Now, if objectified labour were exchanged for living labour, then according to the laws of exchange value the product which = half a day of work could only buy half a day of living labour, even though the worker could live from it for a whole day of work; and if his entire working day were to be bought, then he would have to obtain a whole working day in the product, with which, according to the assumption, he could live for two working days. But on the basis of capital, living labour and done labour do not exchange with one another as exchange values, as identical quantities: the same quantity of labour in objectified form as *value* being equivalent to the same quantity of labour in living form. Rather, what is exchanged is a product, and labour capacity, which is itself a product. Labour capacity is not = to the living labour which it can do, = to the quantity of labour which it can get done – this is its *use value.* It is equal to the quantity of labour by means of which *it must itself be produced* and can be reproduced. The product is thus in fact exchanged not for living labour, but for objectified labour, labour objectified in labour capacity. Living labour itself is a use value possessed by the exchange value [, labour capacity,] which the possessor of the product [, the capitalist,] has acquired in trade, and whether he has acquired less or more of this living labour than he has spent in the form of the product [, wages,] for labour capacity depends on the amount of living labour paid to the worker in the product. If an amount of labour were exchanged for an amount of labour, regardless of whether it were living or objectified, then of course every amount of labour would be equal to itself and its value equal to its amount. The product of half a working day thus could buy only half a working day. But then in fact no *wages* would exist, and no *value of labour.* Labour would have no *value distinct* from that of its product or the equivalent of its product, no *specific* value, and it is precisely the latter which constitutes the *value of labour,* wages.

From the fact, therefore, that a specific quantity of labour = a specific quantity of labour, or also that a specific quantity = itself, from the great discovery that a specific quantity is a specific quantity, Mr Malthus concludes that wages are constant, that the value of labour is constant, namely = to the same amount of labour objectified. This *would be* correct if living labour and stored-up labour were exchanged for one another as *exchange values.* But then there would exist neither *value of labour,* nor *wages,* nor *capital,* nor *wage labour,* nor Malthus's inquiries. All of these are based on the fact that living labour appears as a *use value* and living labour capacity as an *exchange value* opposite the labour stored up in capital. Malthus calmly proceeds: '*The same holds* if *capital and profits enter into the computation of value and the demand for labour varies.'* [14] Here we have the whole profundity. As soon as capital and profits are introduced, living labour capacity begins to be bought, and therefore a smaller portion of stored-up labour is exchanged for a larger portion of living labour. It is a general characteristic of this profundity that the entry of capital, which posits wage labour and which for the first time transforms labour into wage labour and labour capacity into a commodity, introduces no *change* whatever, either into the realization of labour or into the realization of stored-up labour. *Capital, a specific form of the relation of labour to its product and to its value, is, according to Malthus, 'entering' without changing anything.* It is just as if he allowed of no change in the constitution of the Roman Republic other than the introduction, the 'entering of emperors'. He continues: 'If an increased reward of the labourers takes place without an increase in the produce, this is possible only with a fall of profits ... To obtain any given portion of the produce the same quantity of labour is necessary as before, but profit being diminished, the value of the produce is decreased; while this diminution of profits in reference to the value of wages is just counterbalanced by the increased quantity of labour necessary to procure the increased produce awarded to the labourer, leaving the value of labour the same as before.' (p. 33, 34 loc. cit. Notebook IX, 29.) According to the presupposition, the product contains the same quantity of labour. But its value is supposed to have diminished because profits have fallen. However, if the labour time contained in the product has remained the same, how can profits fall? If wages rise while total labour time remains the same – not for momentary causes such as e.g. that competition has become favourable for the workers – then this means nothing other than that the productivity of labour has fallen, that a greater amount of time is necessary to reproduce labour capacity; that, therefore, a larger part of the living labour set in motion by capital falls to necessary labour and a smaller part to surplus labour. Let us leave these trivia for later. Only the following final quotation now for the sake of completeness: ‘Inversely in the opposite case. A smaller quantity of the produce would be awarded to the labourer and profits would rise. A given quantity of produce, which had been obtained by the same quantity of labour as before, would rise in value on account of the rise of profits; while this rise of profits, in reference to the wages of the labourer, would be balanced by the smaller quantity of labour necessary to obtain the diminished produce awarded to the labourer.’ (M. p. 35) (loc. cit. IX, 29.) What he says on this occasion about *money prices in different countries,* proceeding from his principles, to be looked at later. <For example, commodity A can buy one working day; it pays only a half (the necessary half), but it exchanges for the whole. The amount of the total labour purchased by the commodity is then equal to necessary + surplus time. Thus if I know the price of necessary labour = *x,* then the price of the whole labour = 2*x*, and I could in this way appraise the newly created commodity in terms of wages, and thus establish the prices of all commodities in wages. But this would indeed be anything but a *constant value.* Through the confusion that in civilized countries an average time must indeed be worked for wages, say 12 hours, regardless of the wages and regardless of how many of these 12 hours are necessary or surplus labour time, Mr Carey as well – who reduces the amount of labour to working days (and indeed they can be reduced to living work days) – is led to make the assertion that, because the same capital costs constantly less labour time to reproduce, a machine of £100 will, for example, cost after a time only £50 owing to the growth of the productive forces, and hence will be the result of half as much labour time, working days or hours, whichever you like. From this Mr Carey concludes that *the worker* can buy, can obtain *this machine,* with half as many working days as before. [15] He commits the little mistake of regarding the growth of surplus labour time as if it had been gained *for* the worker, whereas the whole matter comes down to just the opposite, namely that the worker spends less of his whole working day working for himself, and more for capital, hence that the objective power of capital grows rapidly over against him, in a specific relation with the increase of the productive forces. Mr Carey lets the worker buy or borrow the machine; in

short, he transforms him into a capitalist. And he is supposed to achieve this increased power over capital precisely because the reproduction of a specific quantity of capital costs less necessary labour, i.e. less paid labour, thus wages fall in relation to profit. In America, as long as the worker there still appropriates a part of his surplus labour for himself, he may accumulate enough to become e.g. a farmer etc. (although that too is already coming to a halt now). In places where wage labour in America can still get somewhere rapidly, this happens through the reproduction of earlier modes of production and property on the foundation of capital (e.g. the independent peasantry). In short, he regards the working days as working days belonging to the worker, and *instead of concluding that he has to produce more capital in order to be employed for the same labour time, he concludes that he has to work less in order to buy the capital* (to appropriate the conditions of production for himself). [16] If he produced 20 machines and can now produce 40 owing to increased productivity, then indeed the single machine becomes cheaper, but, because a smaller part of the working day is necessary in order to produce a given quantity of it, it does not follow that the product of the working day rose for the worker, but rather the reverse, that less living labour is employed for the production of a given quantity of machinery. By the way, Mr Carey, whose aim is *harmony,* himself finds that if the rate of profit declines, then the gross profit rises, because an ever larger capital is required in proportion to employed living labour, and it *therefore* becomes ever more impossible for the worker to appropriate the necessary sum of capital, the minimum of capital required for the productive employment of labour at the new stage of production. A fractional part of the capital requires less labour time for its reproduction, but a larger mass of capital is required in order to realize the lesser labour time. The growth of the productive forces expresses itself in a continuous decline of the part of capital consisting of labour compared with that laid out in advances, machinery etc. Carey’s entire bad joke, which was of course grist to Bastiat’s mill, rests on his transformation of the labour time or working days necessary for production into labour time *belonging* to the worker, whereas this time belongs in fact to capital, and an ever smaller portion of it remains for the worker in proportion to the growth in the productive force of labour. *The less living labour time a given capital has to buy* – or, the greater the total sum of the capital and the less the living labour employed by it relative to its size – the greater, according to Mr Carey, the chance for the worker to become owner of capital, *because* capital is *reproduced by less living labour.* The greater the capital and the smaller the number of workers it employs, relatively, the greater the chance these workers have of becoming capitalists, for has not capital now been reproduced with fewer working days? Cannot it *therefore* also be bought, gained with fewer working days? Take a capital of £100, employing 50 on advances, 50 on labour, and making 50% profit, for the decline of the rate of profit is Carey's chief hobby horse and belongs with his theory. Let each £ in wages be equal to 1 working day = 1 worker. Now take another capital of £16,000, which uses 14,500 in advances, 1,500 in wages (let this also = 1,500 workers) and makes only 20% profit. In the first case the product = 150; in the second (for convenient calculation's sake let the fixed capital turn over in one year) = 19,200 (3,200 profit). Here we have the most advantageous case for Mr Carey. The rate of profit has declined from 50% to 20, i.e. by 3/5 or by 60%. In the one case, a product of 50 is the result of 50 living work days. In the other case, a product of 3,200 by 1,500 workers. In the first case the result of 1 working day a product of 1; in the second the result of 1 working day a product of 2 2/15. In the second case less than half the labour time is necessary to produce a value of 1 as in the first. Now, does this mean that in the second case half the worker's day produces 1/15 for himself, while the other produces only 1 in twice the time, i.e. that he is on the high road to becoming a capitalist? He would first have to acquire a capital of £16,000, and buy alien labour instead of working himself, before this decrease in necessary labour time would aid him in the least. All it has done this way is created an infinite gap between his labour and *the conditions of* its employment, and decreased the rate of *necessary labour,* thus, in proportion to the first relation, thrown more than 6 times as many workers into the street. These workers thrown into the street are now supposed to console themselves with the thought that if they had the conditions to work independently, or rather to work as capitalists, then they themselves would have to hire fewer workers. In the first case the entire capital necessary is £100, and there is more of a chance here for the individual worker in an exceptional case to save up enough, and, with a special combination of luck, himself become a *capitalist* at the same level as capitalist A. The labour time which the worker works is the same with A and B, although the total sum of working days needed by the capitalists is essentially different. For every 6 workers needed by the first capitalist, the second needs not quite 1. The remainder therefore have to work just as much and more surplus time. That capital needs fewer living work days at the stage of production to which it has risen along with the forces of production is the same thing, according to Carey, as that the worker needs fewer working days to appropriate capital for himself; probably with the working days of the un-'occupied' workers.> Because the capitalist needs fewer workers to realize his immense capital, the worker employed by him can, with less labour, make the greater capital his own. Such is the logic of Mr Carey, the harmonizer.

In connection with Ricardo's theory, Wakefield says (Notebook VII, p. 74) loc. cit. p. 231 note:

'Treating labour as a commodity, and capital, the produce of labour, as another, then, if the value of these two commodities were regulated by equal quantities of labour, a given amount of labour would, under all circumstances, exchange for that quantity of capital which had been produced by the same amount of labour; *antecedent* labour would always exchange for the same amount as *present* labour … But the value of labour, in relation to other commodities, in so far, at least, as wages depend upon share, is determined, not by equal quantities of labour, but by the proportion between supply and demand.' [17]

Dormant capital. Increase of production without previous increase of capital. *Bailey*

<Bailey: *Money and its Vicissitudes in Value etc.,* London, 1837 (Notebook V, p. 26 seq.), has remarks about *dormant capital* which can be set in motion through faster circulation (according to him, through a greater volume of currency; he should have said *money)* and tries to demonstrate that if capital were always fully employed in a country, then no increase of demand could bring about an increase of supply. The concept of *dormant capital* belongs within circulation, since capital which is not in circulation is asleep. The relevant quotations are: 'Much capital and productive skill may exist in an inert

state. Those economists are wrong who believe that the number of labourers and the quantity of capital are certain definitive powers who ought inevitably to produce a determinate result in any country where they exist.' (p. 54.) 'Far from the amount of commodities which the existing producers and the existing capital bring to market, being fixed and determined, it is subject to a wide range of variation.' (p. 55.) Thus 'not essential to an increase of production that new capital or new labourers should arise' (e.g. in a country where there is a want of precious metals) ... 'Some commodities or, what is the same, the *power to produce them,* may be in excess at one place, other commodities at another place likewise, and the holder of each wishing to exchange their articles for those held by the other, but kept in a state of non-intercourse for want of a common medium of exchange, and in a state of inaction because they have no motive for production.' (55, 56.) In the circulation of capital, money appears doubly, as the transformation of capital into money as well as realization of the price of the commodity; but here this positing of prices is not a formality. The transformation of the product into money is here the retransformation of capital into *value* as such, independently existing value; capital as money or money as realized capital. Secondly, in the role of mere medium of circulation; this is where it serves merely to retransform capital into the conditions of production. In this second moment, a definite amount of money has to be present at once in the form of wages, as medium of circulation, means of payment. Now the fact that money plays this double role in the circulation of capital makes it appear in all crises as if money were lacking as medium of circulation, whereas capital lacks *value* and hence cannot *monetize* itself. The mass of circulating money may even increase at the same time. A particular section must be made for the new aspects of money when posited as moment of the circulation of capital, partly as the medium of its circulation, partly as *capital's realized value,* as itself *capital;* when we speak of interest etc.> <Bailey continues: 'The labour made active by no means depends on a country's available capital alone. It depends on whether food, tools and raw materials are distributed slowly or rapidly to those parts where it is wanted; whether it circulates with difficulty or not, whether it exists for long intervals in inert masses, and so as a result does not furnish sufficient employment to the population.' (56, 57.) (Gallatin's example, loc. cit. 68, of the western counties of Pennsylvania.) [18] 'Political

economists are inclined to regard a given quantity of capital and a given number of workers as production instruments of a uniform power or operating with a certain uniform intensity … The producer who employs a certain capital may have his products on hand a long time or a short, and while he waits for the occasion to exchange them, his power of producing is stopped or retarded, so that in a given period, such as one year e.g., he may produce only half of what he would, had a prompt demand been present. This remark is equally appropriate to the labourer who is his instrument. The adjustment of the various occupations of men in society to each other must, at least imperfectly, be effected. But there is a wide distance between the stages in which it is realized – every expedient that facilitates traffic is a step towards this adjustment. The more unimpeded and easy the interchange of commodities becomes, the shorter will be those unproductive intervals, in which men, eager for work, seem separated by an impassable barrier from the capital … which, although close at hand, is condemned to barren inertness.' (p. 59–60.) 'General principle, that a new demand will be met by fresh exertions; by the active employment of capital and labour before dormant, and not by the diversion of productive power from other objects. The latter possible only if the employment of capital and labour in a country were capable of no further growth. The exportation of the goods perhaps does not directly set new labour in motion, but it does then absorb commodities on hand as dead stock, and sets at liberty capital tied up in an unproductive state.' (p. 65.) 'Those who assert that an influx of money cannot promote the production of other commodities, since these commodities are the sole agents of production, prove that production cannot be enlarged at all, for it is required for such an enlargement that food, raw materials, and tools should be previously augmented, which in fact is maintaining *that no increase of production can take place without a previous increase'* (but is this not the economic theory of accumulation?) 'or in other words, that an increase is impossible.' (p. 70.) 'Now it is admittedly argued that if the buyer goes to market with an increased quantity of money and if he does not raise the prices of the commodities he finds there, then he gives no additional encouragement to production: if he raises the prices, however, then if prices are proportionally enhanced, the purchasers have no greater power of demand than before.' (73.) 'It is to be denied as a general principle that a purchaser cannot give additional encouragement to production, *unless his demand raise prices ...* Apart from the circumstance that the preparation of a larger quantity admits of a more effective division of labour and the employment of superior machinery, there is in this matter that sort of latitude, arising from a quantity of labour and capital lying unemployed, *and ready to furnish additional commodities at the same rate.* Thus does it happen that a considerable increase of demand often takes place without raising prices.'(73.)>

Wade's *explanation of capital.* [19] *Labour as mere agency of capital.* Capital, collective force. *Civilization, together with my remarks about it. (All social powers of labour as powers of capital. Manufacture. Industry.* Division of labour. *Formal unification of different branches of labour etc. by capital. Accumulation of capital. Transformation of money into capital. Science. Original accumulation and concentration the same. Free and coerced association. Capital as distinct from earlier forms)*

<John Wade: *History of the Middle and Working Classes* etc., 3rd ed., Lond., 1835 (Notebook p. 20) says: 'Labour is the agency by which capital is made *productive of wages, profit, or revenue.*' (p. 161.) 'Capital is stored up industry, provided to develop itself in new and equivalent forms; it is *collective force.*' (p. 162.) 'Capital is only another name for *civilization.*' (164.) Like all productive powers of labour, i.e. those which determine the degree of its intensity and hence of its extensive realization, the association of the workers – the cooperation and division of labour as fundamental conditions of the productivity of labour – appears as the *productive power of capital.* The collective power of labour, its character as social labour, is therefore the *collective power* of capital. Likewise *science.* Likewise the division of labour, as it appears as division of the occupations and of exchange corresponding to them. All social powers of production are productive powers of capital, and it appears as itself their subject. The association of the workers, as it appears in the factory, is therefore not posited by them but by capital. Their combination is not *their* being, but the *being* [*Dasein*] of capital. *Vis-à-vis* the individual

worker, the combination appears accidental. He relates to his own combination and cooperation with other workers as *alien,* as modes of capital's effectiveness. Unless it appears in an inadequate form – e.g. small, self-employed capital – capital already, at a certain greater or lesser stage, presupposes concentration both in objective form, i.e. as concentration in one hand, which here still coincides with accumulation, of the necessaries of life, of raw material and instruments, or, in a word, of money as the general form of wealth; and on the other side, in subjective form, the accumulation of labour powers and their concentration at a single point under the command of the capitalist. There cannot be one capitalist for every worker, but rather there has to be a certain quantity of workers per capitalist, not like one or two journeymen per master. Productive capital, or the mode of production corresponding to capital, can be present in only two forms: manufacture and large-scale industry. In the former, the division of labour is predominant; in the second, the combination of labour powers (with a regular mode of work) and the employment of scientific power, where the combination and, so to speak, the communal spirit of labour is transferred to the machine etc. In the first situation the mass of (accumulated) workers must be large in relation to the amount of capital; in the second the fixed capital must be large in relation to the number of the many cooperating workers. But the concentration of many, and their distribution among the machinery as so many cogs (why it is different in agriculture does not belong here), is, however, already presupposed here. Case II therefore does not need to be specially examined here, but only case I. The development proper to manufacture is the *division of labour.* But this presupposes the (preliminary) gathering-together of many workers under a single command, just as the *process through which money becomes capital presupposes the previous liberation of a certain amount of necessaries of life, raw materials and instruments of labour.* The division of labour is therefore also to be abstracted away here as a later moment. Certain branches of industry, e.g. mining, already presuppose cooperation from the beginning. Thus, so long as capital does not exist, this labour takes place as forced labour (serf or slave labour) under an overseer. Likewise road building etc. In order to take over these works, capital does not create but rather takes over the accumulation and concentration of workers. Nor is this in question.

The simplest form, a form independent of the division of labour, is that capital employs different hand weavers, spinners etc. who live independently and are dispersed over the land. (This form still exists alongside industry.) *Here, then, the mode of production is not yet determined by capital, but rather found on hand by it.* The point of unity of all these scattered workers lies only in their mutual relation with capital, which accumulates the product of their production in its hands and, likewise, the surplus values which they created above and beyond their own revenue. The coordination of their work exists only *in itself,* in so far as each of them works for capital – hence possesses a centre in it – without working together. Their unification by capital is thus merely *formal,* and concerns only the product of labour, not labour itself. Instead of exchanging with many, they exchange only with the one capitalist. This is therefore a *concentration of exchanges* by capital. Capital engages in *exchange* not as an individual, but as representing the consumption and the needs of many. It *no longer exchanges* as individual exchanger, but rather, in the act of exchange, represents society. *Collective exchange* and *concentrative exchange* on the part of capital with the scattered working weavers etc., whose products are collected, united through this exchange, and whose labours are thereby also united, although they proceed independently of one another. The unification of their labours appears as a particular act, alongside which the independent fragmentation of their labours continues. This is the *first condition* necessary for *money* to be exchanged as capital for free labour. The second is the suspension of the independent fragmentation of these many workers., so that the *individual capital* no longer appears towards them merely as *social collective power in the act of exchange,* uniting many exchanges, but rather gathers them in one spot under its command, into one manufactory, and no longer leaves them in the *mode of production found already in existence,* establishing its power on that basis, but rather creates a mode of production corresponding to itself, as its basis. It posits the *concentration* of the workers in production, a unification which will occur initially only in a common location, under overseers, *regimentation, greater discipline, regularity and the* POSITED *dependence in production itself on capital.* Certain *faux frais de production* are thereby saved from the outset. (On this whole process compare Gaskell, where special regard is had to the development of large industry in England.) [20] Now capital appears as the collective force of the workers, their social force, as well as that which ties them together, and hence as the unity which creates this force. Afterwards as before, and at every stage of the development of capital, this all continues to be mediated through the many exchanging with it as the one, so that exchange itself is concentrated in it; the social character of exchange; it exchanges socially with the workers, but they individually with it. With craft production, the main concern is the quality of the product and the particular skill of the individual worker; the master, as master, is supposed to have achieved mastery in this skill. His position as master rests not only on his ownership of the conditions of production, but also on his own skill in the particular work. With the production of capital, and from the very outset, the point is not this half-artistic relation to labour – which corresponds generally with the development of the use value of labour, the development of particular abilities of direct manual work, the formation of the human hand etc. The point from the outset is mass, because the point is exchange value and surplus value. The principle of developed capital is precisely to make special skill superfluous, and to make manual work, directly physical labour, generally superfluous both as skill and as muscular exertion; to transfer skill, rather, into the dead forces of nature. Now, with the presupposition of the rise of manufacture as the rise of the mode of production of capital (slaves are combined in themselves, because under a single master), it is presupposed that the productive force of labour, still to be brought to life by capital, does not yet exist. It is a presupposition, therefore, that necessary labour still takes up a great portion of the entire available labour time in manufacture, hence that surplus labour per individual worker is still relatively small. Now, this is compensated on one side, and the progress of manufactures is correspondingly accelerated, by the fact that the rate of profit is higher, hence that capital accumulates more rapidly in relation to its already existing amount, than it does in big industry. If out of 100 thalers 50 go for labour and surplus time = 1/5, then the value created = 110 or 10%. If out of 100 only 20 went for labour and surplus time = 1/4, then the value created = 105 or 5%. On the other side, manufacture obtains this higher profit rate only through the employment of many workers at once. The greater surplus time can be gained only by collecting together the surplus time of many workers in relation to capital. Absolute, not relative surplus time predominates in manufacture. This is even more the case originally where the scattered, independent workers still realize a part of their own surplus labour for themselves. For capital to exist as capital, to be able to live off profit, as well as to accumulate, its gain must = the sum of the surplus time of many simultaneous living work days. In agriculture, the soil itself with its chemical etc. action is already a machine which makes direct labour more productive, and hence gives a surplus *earlier,* because work is done here at an *earlier* stage with a machine, namely a *natural* one. This the only correct basis of the doctrine of the Physiocrats, which in this respect considers agriculture in comparison with a still quite undeveloped system of manufacture. If the capitalist employed one worker in order to live from that one's surplus time, then he would obviously gain doubly if he himself also worked, with his own funds, for then he would gain, in addition to the surplus time, the wage paid the worker. He would lose in the process. I.e. he would not yet be in the situation of working as a capitalist, or the worker would only be his helper, and thus he would not stand in relation to him as capital.

Thus, in order that money may become transformed into capital, it is necessary not only that it should be able to set surplus labour in motion, but also that there should be a *certain quantity of surplus labour,* the surplus labour of a given mass of necessary labour, i.e. of *many workers* at once, so that their combined sum is sufficient for it not only to lead an existence as *capital,* i.e. to represent wealth in consumption in contrast to the worker's life, but also to set aside surplus labour for accumulation. From the outset, capital does not produce for use value, for immediate subsistence. Surplus labour must therefore be large enough from the beginning to allow a part of it to be re-employed as capital. Thus, whenever the stage is reached where a certain mass of social wealth is already concentrated in one hand, which is objectively capable of appearing as capital, first as the exchange with many workers, later as production by many workers in combination, and is capable of setting a certain quantity of living labour capacities to work simultaneously, then, at that point, production by capital begins, which thus from the outset appears as the *collective force,* the social force, the suspension of individual isolation, first that of exchange with the workers, then that of the workers themselves. The workers' individual isolation still implies their relative independence. Hence their regroupment around the individual capital as the exclusive base of their subsistence implies full dependence on capital, complete dissolution of the ties between the workers and the conditions of production. The result will be the same – or it is the same in another form – when the point of departure is the particular form of exchange which is presupposed for capital to exchange as capital, where money must already *represent many exchangers* or possess a *buying power* surpassing that of the individual and his individual surplus, one which, while belonging to an individual, is already more than individual, and belongs to him as a social function, in his capacity as representative, within exchange, of the social wealth – and it arises on the other side from the conditions of *free labour.* The detachment of the individual from the production conditions of labour = the regroupment of many around one capital. *>

---

* Merchant capital also from the outset the concentration of many exchanges in one hand. It already represents a mass of exchangers both as M and as C.

'This continual progression of knowledge and of experience,' says Babbage, 'is our great power.' [21] This progression, this social progress belongs [to] and is exploited by capital. All earlier forms of property condemn the greater part of humanity, the slaves, to be pure instruments of labour. Historical development, political development, art, science etc. take place in higher circles over their heads. But only capital has subjugated historical progress to the service of wealth.

<Before accumulation by capital, there is presupposed an accumulation which constitutes capital, which is a part of its conceptual determination; we can hardly call it *concentration* yet, because this takes place in distinction to many capitals; but if one still speaks only of capital *generally,* then concentration still coincides with accumulation or with the concept of capital. I.e. it does not yet form a particular aspect. However, capital does indeed exist from the outset as One or Unity as opposed to the workers as Many. And it thus appears as the concentration of workers as distinct from that of work, as a unity falling outside them. In this respect, concentration is contained in the concept of capital – the concentration of many living labour capacities for one purpose;

a concentration which does not in any way need to have been established in production, or penetrated production, at the origin. Centralizing effect of capital on labour capacities, or positing of itself as the independent and external unity of these many available existences.>

<Rossi says in his *Cours d’économie politique* [22] (Notebook, p. 26): ‘Social progress cannot consist in the dissolution of all association, but in the replacement of the forced and oppressive associations of times past by voluntary and equitable associations. The highest degree of isolation is the condition of the savage; the highest degree of forced, oppressive association is barbarism. Apart from these extremes, history shows us a great diversity of varieties and shadings. Perfection is found in voluntary associations, which by their union multiply the forces, without taking away the energy, the morality and the responsibility of individual authority.’ (p. 354.) Under capital, the *association* of workers is not compelled through direct physical force, forced labour, statute labour, slave labour; it is compelled by the fact that the conditions of production are alien property and are themselves present as *objective association,* which is the same as accumulation and concentration of the conditions of production.>

Rossi. *What is capital? Is raw material capital? Wages necessary for it? (Approvisionnement, capital?)*

<The way of conceiving capital in its physical attribute only, as instrument of production, while entirely ignoring the economic form which makes the instrument of production into capital, entangles the economists in all manner of difficulties. Thus Rossi asks, loc. cit. (Notebook, 27): ‘Is the raw material truly an instrument of production? Is it not rather the object on which the productive instruments must act?’ (p. 367.) Thus capital is entirely identical for him here with the instrument of production in the technological sense, according to which every savage is a capitalist. (Which Mr Torrens in fact asserts in the case of the savage who throws a *stone* at a bird.) [23] Incidentally, even from the standpoint of the purely physical abstraction – i.e. of abstraction from the economic category itself – Rossi’s remark is one-sided and shows only that he has not understood his teachers in England. Accumulated labour used as

instrument for new production; or produce pure and simple applied to production; the raw material is employed for production, i.e. submitted to transformation, just as well as the instrument, which is also a product. *The finished result of production in turn becomes a moment of the production process.* The statement means nothing more than that. Within the production process it may figure as raw material or as instrument. But it is an instrument of production not in so far as it serves as an instrument within the direct production process, but rather in so far as it is a means of the renewal of the production process itself – one of its presuppositions. More important and more to the point is the question whether the *approvisionnement* forms a part of capital, i.e. wages, and here the entire confusion of the economists is revealed. ‘It is said that the worker’s payment is capital, because the capitalist advances it him. If all workers’ families had enough to live for a year, there would be no wages. The worker could say to the capitalist: you advance the capital for our common project, and I contribute the labour; the product will be divided among us in such-and-such proportions. As soon as it is realized, each will take his share.’ (p. 369.) ‘Then there would be no advance to the workers. They would nevertheless consume even if the work stood still. What they would consume would belong to the consumption fund, and not at all to capital. Therefore: the advances to the workers are not necessary. *Hence wages is not a constituent element of production. It is an accident, a form of our state of society.* Capital, labour, land, by contrast, are necessary in order to produce. *Secondly*: the word wages is used in a double sense: one says that wages are a capital, but what do wages represent? Labour. He who says wages says labour and vice versa. Thus if the wages advanced are a component of capital, then there would be only two instruments of production to speak of: capital and land.’ (p. 370.) And further: *‘Basically the worker consumes not the capitalist’s possessions but his own; what is given to him as reward of labour is his proportional share of the product.’* (p. 370.) ‘The capitalist’s contract with *the worker is not among the phenomena of production …* The entrepreneur lends himself to this agreement, since it may facilitate production. But this agreement is nothing but a *second operation,* an operation of a quite different nature, grafted onto a productive operation. *In another organization of labour it may disappear.* Even today there are kinds of production where it has no place. The part of the fund which the entrepreneur devotes to the payment of wages does not make up a part of capital … It is a separate operation, which undoubtedly may speed the course of production, but which cannot be termed a *direct* instrument of production.' (370.) 'To conceive labour power, while abstracting from the workers' means of subsistence during production, is to conceive a being existing only in the mind. He who says labour, who says labour power, thereby says worker and means of subsistence, labourer and wages … *the same element reappears under the name of capital; as if the same thing could be simultaneously part of two different instruments of production.'* (370, 371.) Now here there is a great deal of confusion, legitimate because Rossi takes the economists at their word and equates the *instrument of production* as such with capital. First of all he is quite right that wage labour is not an absolute form of labour, but he forgets in the process that capital is not an absolute form of the means and materials of labour either, and that these two forms are two different moments of one and the same form, and hence rise and fall together; that it is nonsensical, therefore, for him to speak of capitalists without wage labourers. [Note] his example of the workers' families who can live for a year without the capitalists, hence are owners of their conditions of production, who perform their necessary labour without the permission of Mr Capitalist. The capitalist whom Rossi has approaching the workers with his proposal thus is no other than a producer of instruments of production – the solicitation means nothing more than a division of labour mediated through exchange with the outside. The two then divide up the common product among themselves even without any agreement – through simple exchange. The exchange is the act of division. A further agreement is not necessary. What these worker families would then exchange would be surplus labour, absolute or relative, made possible for them by the instrument – either new secondary labour in addition to their old labour, from which they could live year after year before the appearance of the c[apitalist], or through the application of the instrument in their old branch of work. Here Mr Rossi makes the worker the owner and vendor of his surplus labour, and has thereby happily extinguished the last trace which might brand him a wage labourer, but has also thereby wiped out the last trace which makes the instrument of production into capital. It is true that the worker 'basically does not consume the capitalist's possessions, but his own', but not exactly as Mr Rossi means, because it is only a *proportional* part of *the* product, but rather because it is a *proportional* part of *his* product, and because, if the semblance of exchange is stripped away, the payment consists of the fact that he works a part of the day for himself and another part for the capitalist, but *only so long as he obtains permission to work at all,* as his work permits this division. The *act of exchange* itself, as we have seen, is not a moment of the direct production process, but rather one of its conditions. Within the total production process of capital, which includes the different moments of its exchanges, its circulation, this exchange is, however, posited as a moment of the total process. But, says Rossi: wages appear twice in the account: once as capital, the other time as labour; thus the wage represents two distinct instruments of production. If the wage represents the instrument of production which is labour, then it cannot represent the instrument of production which is capital. Here another muddle, arising because Rossi takes the orthodox economic distinctions seriously. Wages figure only once in production, as a fund destined to be transformed into wages, as *virtual* wages. As soon as they have become real wages, they are paid out, and then only figure in consumption as the worker's revenue. But what is exchanged for wages is labour capacity, and this does not figure in production at all, but only in the use made of it – *labour.* Labour appears as the instrument of the production of value because it is not paid for, hence not represented by wages. As the activity which creates use values, it likewise has nothing to do with itself as paid labour. In the hand of the worker, the wage is no longer a wage, but a consumption fund. It is wages only in the hand of the capitalist, i.e. the part of capital destined to be exchanged for labour capacity. It has reproduced a saleable labour capacity for the capitalist, so that in this regard even the worker's consumption takes place in the service of the capitalist. He does not pay for labour itself at all, only for labour capacity. This he can do, however, only if this capacity is set to work. If the wage appears twice, it is not because it represents two different instruments of production, but because it appears the first time from the viewpoint of production, the second time from the viewpoint of distribution. This specific form of distribution, however, is not an arbitrary arrangement which could be different; it is, rather, posited by the form of production itself, is only one of its own moments considered from another angle. The value of the machine certainly forms a part of the capital laid out in it; but the machine does not produce, as value, although it brings the manufacturer income. The wage does not represent labour as an instrument of production, any more than value represents the machine as instrument of production. It represents only labour capacity, and, since the latter's value exists separately from it as capital, a part of the capital. In so far as the capitalist appropriates *alien* labour and buys new alien *labour* with it, the wage – i.e. the representative of labour – does, if Mr Rossi wishes to put it this way, appear doubly, (1) as the property of capital, (2) as representative of labour. What actually worries Rossi is that the wage appears as the representative of *two instruments of production,* of *capital* and of *labour;* he forgets that labour as a productive force is incorporated in capital, and that, as *labour in esse,* not *in posse,* [24] it is in no way an *instrument of production* distinct from capital, but is, rather, that without which capital would not be an instrument of production. As for the distinction between wages as forming a part of capital and at the same time the worker's revenue, we will come to that in the section on profit, interest, with which we shall conclude this first chapter on capital.>

Malthus. Theory of value and of wages. (*Capital to do with proportion, labour only with portion. See my remarks on* surplus value *and* profit.) Ricardo's *theory. (Carey contra Ricardo.) Malthus: the wage [has] nothing to [do] with proportion. Malthus's theory of value*

<In connection with the above-mentioned work, *The Measure of Value* etc., Malthus returns to the theme again in his *Definitions in Political Economy* etc., London, 1827. He remarks in the latter: 'No writer that I have met with, anterior to Mr Ricardo, ever used the term *wages* or real wages, as implying *proportions.* Profits, indeed, imply proportions; and the *rate of profits* had always justly been estimated by a *percentage upon the value of the advances.* But wages had uniformly been considered as rising and falling, not *according to any proportion* which they might bear to the whole produce obtained by a certain quantity of labour, but by the greater or smaller quantity

of any particular produce received by the labourer, or by the greater or smaller power which such produce would carry of commanding the necessaries and conveniences of life.' (M. 29, 30.) (Notebook X, p. 49.) The only value produced by capital in a given production is that added by the new amount of labour. This value, however, consists of necessary labour, which reproduces wages – the advances made by capital in the form of wages – and of surplus labour, hence surplus value above and beyond the necessary. The advances made in the form of material and machine are merely transposed from one form into another. The instrument passes into the product just as much as does the raw material, and its wearing-out is at the same time the product's formation. If raw material and instrument cost nothing, as in some extractive industries where they are still almost = 0 (the *raw material* always, in every extractive industry, metal and coal mining, fishing, hunting, lumbering in virgin forests etc.), then they also add absolutely nothing to the value of the production. Their value is the result of previous production, not of the immediate production in which they serve as instrument and material. *Surplus value* can therefore be estimated only in proportion to necessary labour. *Profits* is only a secondary, derivative and transformed form of the surplus value, the bourgeois form, in which the traces of its origin are extinguished. Ricardo himself never grasped this, because he (1) always speaks only of the division of an available, *ready* amount, not of the original positing of this difference; (2) because this understanding would have forced him to see that there is a relation between capital and labour which is entirely different from that of exchange; and he was not allowed the insight that the bourgeois system of equivalents turns into appropriation without equivalent and is based on that; (3) his statement about proportionate profits and wages means only that [if] a certain total value is divided into two portions, any quantity at all is divided in two, then the magnitude of the two parts is necessarily in inverse relation. [25] And then his school justly reduced the matter to this triviality. His aim in asserting the proportionality of wages and profits was not to get to the bottom of the creation of surplus value – for since he begins with the presupposition that a given value is to be divided between wages and profit, between labour and capital, he thereby presupposes this division as self-evident – but rather, firstly, it was to counter the common determination of prices by asserting the correct one, of value, in that he showed that the limit of value is itself not affected by its distribution, different division among profits and wages; *secondly*: to explain not the merely transitory, but rather the continuing decline in the rate of profit, which was inexplicable to him on the presupposition that a fixed portion of value goes to labour; *thirdly*: in explaining the decline of profit by the rise of wages, and the latter in turn by the rise in *value* of agricultural products, i.e. the rising difficulty of their production, thereby at the same time to explain *ground rent* as not being in conflict with his determination of value. This at the same time furnished a polemical weapon for industrial capital, against the exploitation of the progress of industry by landed property. But at the same time, driven by simple logic, he had thereby proclaimed the contradictory nature of profit, of labour and of capital, despite his efforts to convince the worker afterwards that this contradictory character of profit and wages does not influence his real income, and that a proportional (*not* absolute) rise of wages is *harmful* to him, because it hinders accumulation, and the development of industry then benefits only the lazy landowner. Still, the contradictory form had been proclaimed, and Carey, who does not understand Ricardo, could therefore abuse him as the father of the communists etc., where he is again right in a sense he himself does not understand. [26] But the other economists, who, like Malthus, want to have absolutely nothing to do with the proportional (and hence contradictory) nature of wages, *desire* on the one hand to hush up the contradiction; on the other hand they cling to the notion that the worker simply exchanges a specific use value, his labour capacity, for capital, and hence gives up the productive force, the power of labour to create new value, and that he *has nothing to do with the product,* and hence the exchange between capitalists and workers, wages, is concerned, like every simple exchange where economic *equivalents* are presupposed, only with *quantity,* the quantity of use value. As correct as this is in one regard, it also introduces the apparent form of barter, of exchange, so that when competition permits the worker to bargain and to argue with the capitalists, he measures his demands against the capitalists' profit and demands a certain share of the surplus value created by him; so that the *proportion* itself becomes a real moment of economic life itself. Further, in the struggle between the two classes – which necessarily arises with the development of the working class – the measurement of the distance between them, which, precisely, is expressed by wages itself as a proportion, becomes decisively important. The *semblance of exchange* vanishes in the course [*Prozess*] of the mode of production founded on capital. This course itself and its repetition posit what is the case in itself, namely that the worker receives as wages from the capitalist what is only a part of his own labour. This then also enters into the consciousness of the workers as well as of the capitalists. The *question for Ricardo is actually only what proportion of the total value do necessary wages form in the course of development?* It always remains only the *necessary wage;* hence its proportional nature does not interest the worker, who always obtains the same minimum, but only the capitalist, whose deductions from the total income vary, without the workers obtaining a greater amount of use values. But the fact that Ricardo formulated the contradictory nature of profit and wages, even if for quite different purposes, already shows by itself that the mode of production founded on capital had, by his time, taken on a form more and more adequate to its nature. In the cited *Definitions* (Notebook IX, p. 49, 50), Malthus remarks in regard to Ricardo's theory of value: 'Ricardo's assertion, that as the value of wages rises, profits proportionally fall and vice versa, is true only on the presupposition that commodities in which the same amount of labour is contained, are always of the same value, and this is true in 1 case out of 500, and necessarily so, because with the progress of civilization and improvement, the quantity of fixed capital employed steadily grows, and makes more various and unequal the times of the returns of the circulating capital.' (loc. cit. 31, 32.) (This concerns *prices,* not *value*.) Malthus remarks in connection with his own discovery of the true standard of value: '*Firstly*: I had nowhere seen it stated, that the ordinary *quantity of labour which a commodity will command* must represent and measure the *quantity of labour worked up in it, with the addition of profits* ... By representing the labour worked up in a commodity, with the addition of profits, labour represents the natural and necessary conditions of its supply, or the elementary costs of its production ... *Secondly*: I had nowhere seen it stated that, however the fertility of the soil might vary, the elementary costs of producing the wages of a given quantity of labour must always necessarily be the same.' (196, 197.) Means only: wages always equal to the labour time necessary for their production, which varies with the productivity of labour. The quantity of commodities remains the same. 'If one regards value as the general power of purchase of a commodity, then this relates to the purchase of all commodities, of the general mass of commodities. But this is quite unmanageable. ... Now, if any one [should] object, it cannot for a moment be denied that labour best represents an average of the general mass of productions.' (205.) 'A large class of commodities, like raw produce, rise with the progress of society, compared with labour, while the manufactured articles fall. Thus not far from truth to say that the average mass of commodities which a given quantity of labour will command in the same country, during the course of some century, may not very essentially vary.' (206.) 'Value must always be value in exchange for labour.' (224, note, loc. cit.) In other words, the doctrine is: the value of a commodity, the labour worked up in it, is represented by the living work days which it commands, for which it may be exchanged, and hence by *wages.* Living work days contain both time and surplus time. Let us do for Malthus the biggest favour we can do for him. Let us namely assume that the relation of surplus labour to necessary labour, hence the relation of wages to profit, always remains constant. To begin with, the fact that Mr Malthus speaks of the labour worked up in the commodity *with the addition of profits* already demonstrates his confusion, since these profits can form nothing other than a part of the labour worked up. What he has in mind with this *is profits above and beyond labour worked up, which* are supposed to come *out of fixed capital* etc. This can only affect the distribution of the total profit among the different shareholders, but not its total quantity, for if everyone obtained for his commodity the labour worked up in it + profits, then where would these latter come from, Mr Malthus? If one person obtains the labour worked up in his commodity + profit, then the other has to obtain labour worked up − profit, profit here regarded as the excess quantity of real surplus value. This is therefore null and void. Now posit that the labour worked up = 3 working days, and, if the proportion of surplus labour time is as 1:2, then these have been obtained in payment for 1 1/2 working days. The workers indeed worked 3 days, but each of them was paid only half a day. Or, the commodity which they obtain for their 3 days of labour had only 1 1/2 days worked up in it. Thus, all other relations being the same, the capitalist would obtain 6 working days for the 3 working days worked up in his commodity. (The matter is correct only because surplus labour time is posited as = to necessary labour time, hence in the second case *only* the first is repeated.) *(Relative surplus value obviously restricted not only by the relation cited earlier, but also by the degree to which the product enters into the worker's consumption.* If the capitalist could obtain twice the number of *cashmere shawls,* owing to an increase in the productive forces, and if he sold them at their *value,* then he would have created no relative surplus value because the workers do not consume such shawls, and thus the time necessary for the reproduction of their labour capacity would remain the same as before. But this not so in practice, because in such cases the price rises above the value. At this point in the theory it does not concern us yet because capital is here regarded in itself, not in a particular branch.) That means, he will pay the wages of 3 days and get 6 days of work; with each 1/2 day he buys a day; hence with 6/2 days, = 3 days, 6 days. To assert, then, that the working days a commodity commands, or the wages it pays, express its value is to understand absolutely nothing of the nature of capital and wage labour. It is the pith of all value-creation and of capital-creation that objectified working days command a greater number of living ones. It would have been correct if Malthus had said that the living labour time a commodity commands expresses the measure of its *realization,* the measure of the *surplus labour* it posits. But this would only be the tautology that it posits more labour to the extent that it posits more, or it would be the expression of the opposite of what Malthus wants, that surplus value arises because the living labour time a commodity commands never represents the labour worked up in it. (Now we have finally done with Malthus.)>

Aim of capitalist production value (money), not commodity, use value etc. Chalmers. [27] – *Economic cycle. – Circulation process.* Chalmers

<We have demonstrated above, in the development of the concept of capital, that it is value as such, *money,* which both preserves itself through circulation and also increases itself through exchange with living labour. That, hence, the aim of producing capital is *never use value,* but rather the general form of wealth as wealth. The cleric Th. Chalmers, in the otherwise in many respects ridiculous and repulsive work: *On Political Economy in Connection with the Moral State and Moral Prospects of Society,* 2nd. ed., Lond., 1832, has correctly struck upon this point, without at the same time falling into the asininity of types like Ferrier etc., who confuse money as the value of capital with the really available metallic money. [28] In crises, capital (as commodity) is not exchangeable, not because *too few* means of circulation are available; but, rather, it does not circulate because it is *not exchangeable.* The importance assumed by cash in times of crisis arises only because, while capital is not exchangeable for its value – and only for that reason does its value appear opposite it in the money form – there are obligations to pay off; alongside the interrupted circulation a *forced circulation* takes place. Chalmers says (Notebook IX, p. 57): 'When a consumer refuses certain commodities, it is not always, as is assumed by the new economists, because he wants to purchase others in preference, but because he wants to reserve entire the general power of purchasing. And when a *merchant* brings commodities to market, it is generally not in quest of other commodities to be given in return for them ... he will extend his *general power of purchase of all commodities.* It is useless to say that money is also a *commodity.* The real metallic money for which a merchant has any use does not amount to more than a small *fraction of his capital,* even of *his monied capital;* all of which, though estimated in money, can be made, on the strength of written contracts, to describe its orbit, and be effective for all its purposes, with the aid *of coin amounting to an insignificant proportion of the whole. The great object of the monied capitalist,* in fact, is to add to the *nominal amount of his fortune.* It is that, if expressed pecuniarily this year by £20,000 e.g., it should be expressed

pecuniarily next year by £24,000. *To advance his capital, as estimated in money,* is the only way in which he can advance his interest as a merchant. The importance of these objects for him is not affected by fluctuations in the currency or by a change in the real value of money. For example, in one year he comes from 20 to 24,000 pounds; through a fall in the value of money he may not have increased his command over the comforts etc. Nevertheless, this is his interest just as much as if money had not fallen; for else his monied fortune would have remained stationary and his real wealth would have declined in the proportion of 24 to 20 … *Commodities'* (i.e. use value, real wealth) 'thus not the terminating object of the trading capitalist.' (The illusion of the Monetary System, however, was that it regarded real metallic money (or paper, would change nothing), in short, the *form* of value, as *real money,* as the *general form of wealth* and of self-enrichment, whereas precisely as *money* increases as the accumulation of general power of purchase, it undergoes a relative decline in its specific form as medium of exchange or also as *realized hoard.)* As *assignation* in real wealth or productive power [the capitalist's money] gains a thousand forms, *'quite apart from expenditure of his revenue in purchases for the sake of consumption.* In the *outlay of his capital,* and *when he purchases for the sake of production,* money is his terminating object' (not *coin, nota bene).* (164–6.)

'Profit,' says the same Chalmers, 'has the effect of attaching the services of the disposable population to other masters, besides the mere landed proprietors, … while their expenditure reaches higher than the necessaries of life.' (78. Notebook IX, p.53.)>

In the book just referred to, Chalmers calls the whole *circulation process* the economic cycle: 'The world of trade may be conceived to revolve in what we shall call an economic cycle, which accomplishes one revolution by business coming round again, through its successive transactions, to the point from which it set out. Its commencement may be dated from the point at which the capitalist has obtained those returns by which his capital is replaced to him: whence he proceeds anew to engage his workmen; to distribute among them, in wages, their maintenance, or rather the power of lifting it; to obtain from them in finished work, the articles in which he specially deals; to bring these articles to market, and there terminate the orbit of one set of movements, by effecting a sale, and receiving in its proceeds, a return for the whole outlays of the period. The intervention of money alters nothing in the real character of this operation … ' (85 loc. cit.) (Notebook, p. 54, 55.)

Difference in return. ***Interruption of the production process (or rather its failure to coincide with the labour process). Total duration of the production process. (Agriculture. Hodgskin.)*** **Unequal periods of production**

The difference in the return, in so far as it depends on the phase of the circulation process which coincides with the direct production process, depends not only on the longer or shorter labour time required to complete the article (e.g. canal building etc.), but also, in certain branches of industry – agriculture – on the interruptions of the work which are due to the nature of the work itself, where on the one hand the capital lies fallow, and, on the other, labour stands still. Thus the example given by A. Smith, that wheat is a crop taking 1 year, the ox a crop taking 5 years, etc. [29] Therefore 5 years of labour are employed on the latter, only 1 on the former. Little labour is employed e.g. on cattle raised on pasture. At the same time, in agriculture, the labour applied e.g. during the winter is also little. In agriculture (and to a greater or lesser degree in many another branch of production) there are interruptions given by the conditions of the production process itself, pauses in labour time, which must be begun anew at the given point in order to continue or to complete the process; the constancy of the production process here does not coincide with the continuity of the labour process. This is one moment of the difference. *Secondly*: the product generally requires a longer time to be *completed,* to be put into its finished state; this is the total duration of the production process, regardless of whether interruptions take place in the operations of labour or not; the different duration of the production phase generally. *Thirdly*: after the product is finished, it may be necessary for it to lie idle for some time, during which it needs relatively little labour, in order to be left in the care of natural processes, e.g. wine. (This will be, conceptually, approximately the same case as I.) *Fourthly*: a longer time to be brought to market, because destined for a more distant market. (This coincides conceptually with case II.) *Fifthly*: The shorter or longer period of the total return of a capital (its total reproduction), in so far as it is determined by the relation of fixed capital and circulating capital, is concerned obviously not with the *immediate production process* and its duration, but rather takes its character from circulation. The total capital's period of reproduction is determined by the total process, circulation included.

'Inequality in the periods necessary for production.' [30]

'The *difference of time* required to complete the products of agriculture, and of other species of labour, is the main cause of the great dependence of the agriculturists. They cannot bring their commodities to market in less time than a year. For that whole period they are obliged to borrow from the shoemaker, the tailor, the smith, the wheelwright and the various other labourers, whose products they need and which are completed in a few days or weeks. Owing to this natural circumstance, and owing to the more rapid increase of the wealth produced by other labour than that of agriculture, the monopolizers of all the land, although they have also monopolized the legislation, are unable to save themselves and their servants, the farmers, from being the most dependent class in the community.' (Thomas Hodgskin, *Popular Polit. Econ.* Four lectures etc. London, 1827, p. 147 note.) (Notebook IX, p. 44.) 'The natural circumstance of all commodities being produced in unequal periods, while the wants of the labourer must be supplied daily ... This inequality in the time necessary to complete different commodities, would in the savage state cause the hunter etc. to have a surplus of game etc., before the maker of bows and arrows etc. had any commodity completed to give for the surplus game. No exchange could be made; the bow-maker must be also a hunter and division of labour impossible. This difficulty contributed to the invention of money.' (179, 180.) (loc. cit.)

The concept of the free labourer contains the pauper. *Population and overpopulation etc.*

<It is already contained in the concept of the *free labourer,* that he is a *pauper:* virtual pauper. According to his economic conditions he is merely a *living labour capacity,* hence equipped with the necessaries of life. Necessity on all sides, without the objectivities necessary to realize himself as labour capacity. If the capitalist has no use for his surplus labour, then the worker may

not perform his necessary labour; not produce his necessaries. Then he cannot obtain them through exchange; rather, if he does obtain them, it is only because alms are thrown to him from revenue. He can live as a worker only in so far as he exchanges his labour capacity for that part of capital which forms the labour fund. This exchange is tied to conditions which are accidental *for him,* and indifferent to his *organic* presence. He is thus a virtual pauper. Since it is further the condition of production based on capital that he produces ever more surplus labour, it follows that ever more *necessary labour* is set free. Thus the chances of his pauperism increase. To the development of surplus labour corresponds that of the surplus population. In different modes of social production there are different laws of the increase of population and of overpopulation; the latter identical with pauperism. These different laws can simply be reduced to the different modes of relating to the conditions of production, or, in respect to the living individual, the conditions of his reproduction as a member of society, since he labours and appropriates only in society. The dissolution of these relations in regard to the single individual, or to part of the population, places them outside the reproductive conditions of this specific basis, and hence posits them as overpopulation, and not only lacking in means but incapable of appropriating the necessaries through labour, hence as paupers. Only in the mode of production based on capital does pauperism appear as the result of labour itself, of the development of the productive force of labour. Thus, what may be overpopulation in one stage of social production may not be so in another, and their effects may be different. E.g. the colonies sent out in antiquity were overpopulation, i.e. their members could not continue to live in the same space with the material basis of property, i.e. conditions of production. The number may appear very small compared with the modern conditions of production. They were, nevertheless, very far from being paupers. Such was, however, the Roman plebs with its bread and circuses. The overpopulation which leads to the great migrations presupposes different conditions again. Since in all previous forms of production the development of the forces of production is not the basis of appropriation, but a specific relation to the conditions of production (forms of property) appears as *presupposed barrier* to the forces of production, and is merely to be reproduced, it follows that the development of population, in which the development of all productive forces is summarized, must even more strongly encounter an *external barrier* and thus appear as something to be restricted. The conditions of the community [were] consistent only with a specific amount of population. On the other side, if the barriers to population posited by the elasticity of the specific form of the conditions of production *change in consequence of the latter, if they contract or expand* – thus overpopulation among hunting peoples was different from that among the Athenians, in turn different among the latter from that among the Germanic tribes – then so does the absolute rate of population increase, and hence the rate of overpopulation and population. The amount of overpopulation posited on the basis of a specific production is thus just as determinate as the adequate population. Overpopulation and population, taken together, are *the* population which a specific production basis can create. The extent to which it goes beyond its barrier is given by the barrier itself, or rather by the same base which posits the barrier. Just as necessary labour and surplus labour together [are] the whole of labour on a given base.

Malthus's theory, which incidentally not his invention, but whose fame he appropriated through the clerical fanaticism with which he propounded it – actually only through the weight he placed on it – is significant in two respects: (1) because he gives brutal expression to the brutal viewpoint of capital; (2) because he *asserted* the fact of overpopulation in all forms of society. Proved it he has not, for there is nothing more uncritical than his motley compilations from historians and travellers' descriptions. His conception is altogether false and childish (1) because he regards *overpopulation* as being *of the same kind* in all the different historic phases of economic development; does not understand their specific difference, and hence stupidly reduces these very complicated and varying relations to a single relation, two equations, in which the natural reproduction of humanity appears on the one side, and the natural reproduction of edible plants (or means of subsistence) on the other, as two natural series, the former geometric and the latter arithmetic in progression. In this way he transforms the historically distinct relations into an abstract numerical relation, which he has fished purely out of thin air, and which rests neither on natural nor on historical laws. There is allegedly a natural difference between the reproduction of mankind and e.g. grain. This baboon thereby implies that the *increase of humanity* is a purely natural process, which requires *external restraints, checks,* to prevent it from proceeding in geometrical progression. This *geometrical reproduction* is the natural reproduction process of mankind. He would find in history that population proceeds in very different relations, and that overpopulation is likewise a historically determined relation, in no way determined by abstract numbers or by the absolute limit of the productivity of the necessaries of life, but by limits posited rather by *specific conditions of production.* As well as restricted numerically. How small do the numbers which meant overpopulation for the Athenians appear to us! Secondly, restricted according to character. An overpopulation of free Athenians who become transformed into colonists is significantly different from an overpopulation of workers who become transformed into workhouse inmates. Similarly the begging overpopulation which consumes the surplus produce of a monastery is different from that which forms in a factory. It is Malthus who abstracts from these specific historic laws of the movement of population, which are indeed the history of the nature of humanity, the *natural* laws, but natural laws of humanity only at a specific historic development, with a development of the forces of production determined by humanity's own process of history. Malthusian man, abstracted from historically determined man, exists only in his brain; hence also the geometric method of reproduction corresponding to this natural Malthusian man. Real history thus appears to him in such a way that the reproduction of his natural humanity is not an abstraction from the historic process of real reproduction, but just the contrary, that real reproduction is an application of the Malthusian theory. Hence the inherent conditions of population as well as of overpopulation at every stage of history appear to him as a series of *external checks* which have *prevented* the population from developing in the Malthusian form. The conditions in which mankind historically produces and reproduces itself appear as *barriers* to the reproduction of the Malthusian natural man, who is a Malthusian creature. On the other hand, the production of the necessaries of life – as it is checked, determined by human action – appears as a *check* which it posits to itself. The ferns would cover the entire earth. Their reproduction would stop only where space for them ceased. They would obey no arithmetic proportion. It is hard to say where Malthus has discovered that the reproduction of voluntary natural products would stop for intrinsic reasons, without *external checks.* He transforms the immanent, historically changing limits of the human reproduction process into *outer barriers;* and the *outer barriers* to natural reproduction into *immanent limits* or *natural laws* of reproduction.

(2) He stupidly relates a specific quantity of people to a specific quantity of necessaries. [31] Ricardo immediately and correctly confronted him with the fact that the quantity of grain available is completely irrelevant to the worker if he has no *employment;* that it is therefore the means of employment and not of subsistence which put him into the category of surplus population. [32] But this should be conceived more generally, and relates to the *social mediation* as such, through which the individual gains access to the means of his reproduction and creates them; hence it relates to the *conditions of production* and his relation to them. There was no barrier to the reproduction of the Athenian slave other than the producible necessaries. And we never hear that there were *surplus slaves* in antiquity. The call for them increased, rather. There was, however, a surplus population of non-workers (in the immediate sense), who were not too many in relation to the necessaries available, but who had lost the conditions under which they could appropriate them. The invention of surplus labourers, i.e. of propertyless people who work, belongs to the period of capital. The beggars who fastened themselves to the monasteries and helped them eat up their surplus product are in the same class as the feudal retainers, and this shows that the surplus produce could not be eaten up by the small number of its owners. It is only another form of the retainers of old, or of the menial servants of today. The overpopulation e.g. among hunting peoples, which shows itself in the warfare between the tribes, proves not that the earth could not support their small numbers, but rather that the condition of their reproduction required a great amount of territory for few people. Never a relation to a *non-existent* absolute mass of means of subsistence, but rather relation to the conditions of reproduction, of the production of these means, including likewise the *conditions of reproduction of human beings,* of the total population, of relative surplus population. This surplus purely relative: in no way related to the *means of subsistence as* such, but rather to the mode of producing them. Hence also only a *surplus* at this state of development.

(3) What is not actually proper to Malthus at all, the introduction of the

theory of rent – at bottom only a formula for saying that in the stage of industry familiar to Ricardo etc., agriculture remained behind industry, which incidentally inherent in bourgeois production although in varying relations – does not belong here.>

Necessary labour. Surplus labour. Surplus population. Surplus capital

<As to production founded on capital, the greatest absolute mass of necessary labour together with the greatest relative mass of surplus labour appears as a condition, regarded absolutely. Hence, as a fundamental condition, maximum growth of population – of living labour capacities. If we further examine the conditions of the development of the productive forces as well as of exchange, division of labour, cooperation, all-sided observation, which can only proceed from many heads, science, as many centres of exchange as possible – all of it identical with growth of population. On another side, it is also inherent in the condition of the appropriation of alien surplus labour that, in addition to the necessary population – i.e. that which represents necessary labour, labour necessary for production – there should be a *surplus population,* which does not work. The further development of capital shows that besides the industrial part of this surplus population – the industrial capitalist – a purely consuming part branches off: idlers, whose business it is to consume alien products and who, since crude consumption has its limits, must have the products furnished to them partly in refined form, as luxury products. This idle surplus population is not what the economists have in mind when they speak of surplus population. On the contrary, it – and its business of consuming – is treated by the population fanatics as precisely the necessary population, and justly (logically) so. The expression, surplus population, concerns exclusively labour capacities, i.e. the *necessary population;* surplus of *labour capacities.* But this arises simply from the nature of capital. Labour capacity can perform its necessary labour only if its surplus labour has value for capital, if it can be realized by capital. Thus, if this realizability is blocked by one or another barrier, then (1) *labour capacity* itself appears *outside the conditions of the reproduction of its existence;* it exists without the *conditions of its existence,* and is therefore a mere encumbrance; needs without the means to satisfy them; (2) necessary

labour appears as superfluous, because the superfluous is not necessary. It is necessary only to the extent that it is the condition for the realization of capital. Thus the relation of necessary and surplus labour, as it is posited by capital, turns into its opposite, so that a part of necessary labour – i.e. of the labour reproducing labour capacity – is superfluous, and this labour capacity itself is therefore used as a *surplus* of the necessary working population, i.e. of the portion of the working population whose necessary labour is not superfluous but necessary for capital. Since the necessary development of the productive forces as posited by capital consists in increasing the relation of surplus labour to necessary labour, or in decreasing the portion of necessary labour required for a given amount of surplus labour, then, if a definite amount of labour capacity is given, the relation of *necessary* labour needed by capital must necessarily continuously decline, i.e. part of these labour capacities must become superfluous, since a portion of them suffices to perform the quantity of surplus labour for which the whole amount was required previously. The positing of a specific portion of labour capacities as superfluous, i.e. of the labour required for their reproduction as superfluous, is therefore a necessary consequence of the growth of surplus labour relative to necessary. The decrease of relatively necessary labour appears as increase of the relatively superfluous labouring capacities – i.e. as the positing of surplus population. If the latter is supported, then this comes not out of the labour fund but out of the revenue of all classes. It takes place not through the labour of the labour capacity itself – no longer through its normal reproduction as worker, but rather the worker is maintained as a living being through the mercy of others; hence becomes a tramp and a pauper; because he no longer sustains himself through his necessary labour; hence, through the exchange with a part of capital; he has fallen out of the conditions of the relation of apparent exchange and apparent independence; secondly: society in its fractional parts undertakes for Mr Capitalist the business of keeping his virtual instrument of labour – its wear and tear – intact as reserve for later use. He shifts a part of the reproduction costs of the working class off his own shoulders and thus pauperizes a part of the remaining population for his own profit. At the same time, capital has the tendency both to posit and equally to suspend this pauperism, because it constantly reproduces itself as surplus capital. It acts in opposite directions, so that sometimes one, sometimes the other is predominant. Finally, the positing of surplus capital contains a double moment: (1) It requires a growing population in order to be set into motion; if the relative population it requires has become smaller, then it has itself become correspondingly larger; (2) it requires a part of the population which is unemployed (at least relatively); i.e. a relative surplus population, in order to find the readily available population for the growth of surplus capital; (3) at a given stage of the productive forces, the surplus value may be present, but not yet in the proportions sufficient to be employed as capital. Not only a minimum of the stage of production, but posited for its expansion. In this case surplus capital and surplus population. Likewise, a surplus population may be present, but not enough, not in the proportions required for more production. In all these investigations, the variations in sales, contraction of the market etc., in short, everything which presupposes the *process of many capitals,* has been intentionally abstracted away.>

A. Smith. *Work as sacrifice. (Senior's theory of the capitalist's sacrifice.) (Proudhon's surplus.)* – A. Smith. Origin of profit. *Original accumulation*. Wakefield. – *Slave and free labour*. – Atkinson. – *Profit*. – *Origin of* profit. MacCulloch.

<A. Smith's view, [is] that *labour never changes its value,* in the sense that a *definite amount of labour* is always a definite *amount of labour for the worker,* i.e., with A. Smith, a sacrifice of the *same quantitative magnitude.* Whether I obtain much or little for an hour of work – which depends on its productivity and other circumstances – I have *worked* one hour. What I have had to pay for the result of my work, my wages, is always the same *hour of work,* let the result vary as it may. 'Equal quantities of labour must at all times and in all places have the same value for the worker. In his normal state of health, strength and activity, and with the common degree of skill and facility which he may possess, he must always give up the *identical portion of his tranquillity, his freedom,* and his *happiness.* Whatever may be the quantity or composition of the commodities he obtains in reward of his work, the *price he pays* is always the same. Of course, this price may buy sometimes a lesser, sometimes a greater quantity of these commodities, but only because their

value changes, not the value of the labour which buys them. Labour alone, therefore, never changes its own value. It is therefore the *real price* of commodities, money is only their nominal value.' (ed. by Garnier, Vol. I, pp. 64–6.) (Notebook, p. 7.) [33] In the sweat of thy brow shalt thou labour! was Jehovah's curse on Adam. [34] And this is labour for Smith, a curse. 'Tranquillity' appears as the adequate state, as identical with 'freedom' and 'happiness'. It seems quite far from Smith's mind that the individual, 'in his normal state of health, strength, activity, skill, facility', also needs a normal portion of work, and of the suspension of tranquillity. Certainly, labour obtains its measure from the outside, through the aim to be attained and the obstacles to be overcome in attaining it. But Smith has no inkling whatever that this overcoming of obstacles is in itself a liberating activity – and that, further, the external aims become stripped of the semblance of merely external natural urgencies, and become posited as aims which the individual himself posits – hence as self-realization, objectification of the subject, hence real freedom, whose action is, precisely, labour. He is right, of course, that, in its historic forms as slave-labour, serf-labour, and wage-labour, labour always appears as repulsive, always as *external forced labour;* and not-labour, by contrast, as 'freedom, and happiness'. This holds doubly: for this contradictory labour; and, relatedly, for labour which has not yet created the subjective and objective conditions for itself (or also, in contrast to the pastoral etc. state, which it has lost), in which labour becomes attractive work, the individual's self-realization, which in no way means that it becomes mere fun, mere amusement, as Fourier, with *grisette*-like [35] naïveté, conceives it. [36] Really free working, e.g. composing, is at the same time precisely the most damned seriousness, the most intense exertion. The work of material production can achieve this character only (1) when its social character is posited, (2) when it is of a scientific and at the same time general character, not merely human exertion as a specifically harnessed natural force, but exertion as subject, which appears in the production process not in a merely natural, spontaneous form, but as an activity regulating all the forces of nature. A. Smith, by the way, has only the slaves of capital in mind. For example, even the semi-artistic worker of the Middle Ages does not fit into his definition. *But* what *we* want *here initially* is not to go into his view on labour, his philosophical view, but into the economic moment. Labour regarded merely as a *sacrifice,* and hence value-positing, as a *price* paid for things and hence giving them price depending on whether they cost more or less labour, is a purely *negative* characterization. This is why Mr Senior, for example, was able to make capital into a source of production in the same sense as labour, a source *sui generis* of the production of *value,* because the capitalist too brings a *sacrifice,* the sacrifice of *abstinence,* in that he grows wealthy instead of eating up his product directly. [37] Something that is merely negative creates nothing. If the worker should, e.g. enjoy his work – as the miser certainly enjoys Senior's *abstinence* – then the product does not lose any of its value. Labour *alone* produces; it is the only *substance* of products as *values.* * Its measure, labour time – presupposing equal intensity – is therefore the measure of values. The qualitative difference between workers, in so far as it is not natural, posited by sex, age, physical strength etc. – and thus basically expresses not the qualitative value of labour, but rather the division and differentiation of labour – is itself only a product of history, and is in turn suspended for the great mass of labour, in that the latter is itself simple; while the qualitatively higher takes its economic measure from the simple. The statement that *labour time,* or the amount of labour, is the measure of values means nothing other than that the measure of labour is the measure of values. Two things are only commensurable if they are of the *same nature.* Products can be measured with the measure of labour – labour time – only because they are, by their nature, *labour.* They are objectified labour. As objects they assume forms in which their being as labour may certainly be apparent in their form (as a purposiveness posited in them from outside; however, this is not at all apparent with e.g. the ox, or with reproduced natural products generally), but in which this being has, apart from itself, no other features in common. They exist as equals as long as they exist as activity. The latter is measured by time, which therefore also becomes the measure of objectified labour. We will examine elsewhere to what extent this *measurement* is linked with exchange, not with organized social labour – a definite stage of the social production process. Use value is not concerned with human activity as the source of the product, with its having been posited by human activity, but with its being for mankind. In so far as the product has a measure for itself, it is its natural measure as natural object, mass, weight, length, volume etc. Measure of utility etc. But as effect, or as static presence of the force which created it, it is measured only by the measure of this force itself. The measure of labour is time. Only because products ARE labour can they be measured by the measure of labour, by labour time, the amount of labour consumed in them. The negation of tranquillity, as mere negation, ascetic sacrifice, creates nothing. *Someone may castigate and flagellate himself all day long like the monks etc., and this quantity of sacrifice he contributes will remain totally worthless.* The *natural price* of things is not the sacrifice made for them. This recalls, rather, the pre-industrial view which wants to achieve wealth by sacrificing to the gods. There has to be something besides sacrifice. The sacrifice of tranquillity can also be called the sacrifice of laziness, unfreedom, unhappiness, i.e. negation of a negative state. A. Smith considers labour psychologically, as to the fun or displeasure it holds for the individual. But it is something else, too, in addition to this *emotional* relation with his activity – firstly, for others, since A's mere sacrifice would be of no use for B; secondly, a definite relation by his own self to the thing he works on, and to his own working capabilities. It is a *positive, creative activity.* The measure of labour – time – of course does not depend on labour's productivity; its measure is precisely nothing but a unit of which the proportional parts of labour express a certain multiple. It certainly does not follow from this that the *value* of labour is constant; or, follows only in so far as equal quantities of labour are of the same measured magnitude. It is then found upon further examination that the values of products are measured not by the labour employed in them, but by the labour necessary for their production. Hence not sacrifice, but labour as a condition of production. The equivalent expresses the condition of the products' reproduction, as given to them through exchange, i.e. the possibility of repeating productive activity anew, as posited by its own product.> <By the way, Smith's view of labour as a *sacrifice,* which incidentally correctly expresses the *subjective relation of the wage worker to his own activity,* still does not lead to what he wants – namely the determination of value by labour time. An hour of work may always be an equal sacrifice for the worker. But the value of commodities in no way depends on his feelings; nor does the value of his hour of work. Since A. Smith admits that one can buy this sacrifice sometimes more cheaply, sometimes more dearly, it becomes distinctly peculiar

that it is supposed always to be *sold* for the same price. And he is indeed inconsistent. Later he makes *wages* the measure of value, not the amount of labour. *The slaughter of the ox is always the same sacrifice, for the ox. But this does not mean that the value of beef is constant.*> <'Now, although equal quantities of labour always have the same value as regards the worker, they appear sometimes of smaller, sometimes of larger value for him who employs the worker. He purchases them sometimes with a smaller, sometimes a larger quantity of commodities. For him, therefore, the price of labour varies like that of any other thing, although in reality it is only the commodities which are sometimes dearer, sometimes cheaper.' (p. 66 A. Smith, loc. cit. Vol. I.) (Notebook, p. 8.)>

[*] Proudhon's lack of understanding of this matter is evident from his axiom that every labour leaves a surplus. [38] What he denies for capital, he transforms into a natural property of labour. The point is, rather, that the labour time necessary to meet absolute needs leaves *free* time (different at the different stages of the development of the productive forces), and that therefore a surplus product can be created if *surplus labour* is worked. The aim is to suspend the relation itself, so that the surplus product itself appears as necessary. Ultimately, material production leaves everyone surplus time for other activity. There is no longer anything mystical in this. Originally, the free gift of nature abundant, or at least merely to be appropriated. From the outset, naturally arisen association (family) and the division of labour and cooperation corresponding to it. For needs are themselves scant at the *beginning*. They too develop only with the forces of production.

<The way in which A. Smith lets profit arise is very naïve. 'In the primitive state, the product of labour belongs wholly to the worker. The quantity' (including also the greater difficulty etc.) 'of labour employed to obtain or to produce an exchangeable object is the *only circumstance* which governs the quantity of labour which this object can on the average buy, command or obtain in exchange ... BUT *as soon as a stock* accumulates in the hands of *private persons, the value which the workers add to the object dissolves into two parts,* of which one pays their wages, the other the profit which the entrepreneur makes on the sum of the stock which has served him to advance these wages and the materials of labour. He would have *no interest* in employing these workers if he did not expect from the sale of their works

something more than is necessary to replace this fund, and he would have no interest in employing a larger in preference over a small amount of funds if his profit did not stand in some proportion to the volume of the funds employed.' (loc. cit. p. 96, 97.) (N., p. 9.) (See A. Smith's peculiar view that *before the division of labour,* 'where every one produced everything necessary, no stock was necessary'. As if, in this state, while he finds no stock in nature, he would not have to find the objective conditions of life, in order to work. Even the savage, even animals, set aside a reserve. Smith can at most have in mind a situation in which the impulse to labour is still a direct, momentary instinct, and then a *stock* still has to be present in nature in one way or another *without labour.* (Notebook, p. 19.) (Smith is confused here. *Concentration of the stock* in a single hand then not necessary.)>

<In Vol. III of his edition of A. Smith, Wakefield remarks: 'The labour of slaves being combined, is more productive than the much divided labour of freemen. The labour of freemen is more productive than that of slaves, only when it comes to be combined *by means of greater dearness of land, and the system of hiring for wages.'* (Note to p. 18.) (Notebook VIII, p. 1.) 'In countries where land remains very cheap, either all the people are in a state of barbarism, or some of them are in a state of slavery.' (Note to p. 20.)>

<*'Profit* is a term signifying the increase of capital or wealth; so, failing to find the laws which govern the rate of profit, is failing to find the laws of the formation of capital.' (p. 55. Atkinson (W.), *Principles of Political Economy,* London, 1840.) (Notebook, p. 2.)>

<'Man is as much the *produce of labour* as any of the machines constructed by his agency; and it appears to us that in all economical investigations he ought to be considered in precisely the same point of view. Every individual who has arrived at maturity ... may, with perfect propriety, be viewed as a machine which it has cost 20 years of assiduous attention and the expenditure of a considerable capital to construct. And if a further sum is laid out for his education or qualification for the exercise of a business etc., his value is proportionally increased, just as a machine is made more valuable through the expenditure of additional capital or labour in its construction, in order to give it new powers.' (McCulloch, *The Principles of Pol. Econ.,* London, 1825, p. 115.) (Notebook, p. 9.)> <'In point of fact, a commodity will

always exchange for more' labour (than it was produced by): 'and it *is this excess that constitutes profits.'* (p. 221, McCulloch loc. cit.) (Notebook, p. 13.) The same gentle McCulloch, about whom Malthus rightly says that he sees it as the proper task of science to equate everything with everything else, [39] says: '*the profits of capital* are only another name for the wages of *accumulated labour*' (p. 291) (loc. cit. Notebook, 14) and hence no doubt the wages of labour are only another name for the profits of living capital. 'Wages … really consist of a *part of the produce of the industry of the labourer;* consequently, they have a high real value if the labourer receives a comparatively high share of the product of his industry, and vice versa.' (295 loc. cit.) (Notebook, p. 15.)>

Surplus labour. Profit. Wages. *Economists. Ramsay. Wade*

The positing of *surplus labour* through capital has on the whole been so little understood by the economists that they present striking phenomena of its occurrence as something *special,* as a curiosity. Thus Ramsay, with night work. Likewise John Wade e.g., in *History of the Middle and Working Classes,* 3rd ed., London, 1835 (p. 241) (Notebook, p. 21) says: 'The standard of wages is *also* connected with the hours of work and rest periods. It was the policy of the masters in recent years' (before 1835) 'to usurp on operatives in this respect, by cutting or abridging holidays and mealtimes and gradually stretching the hours of work; knowing that an increase of 1/4 in the time of work is equivalent to a reduction in wages by the same amount.'

Immovable capital. *Return of capital. Fixed capital.* John St. Mill

John St. Mill: *Essays on Some Unsettled Questions of Political Economy,* London, 1844. (The few original ideas of Mill Junior are contained in this narrow little volume, not in his fat, pedantic *magnum opus.)*

'Whatever is destined to be employed reproductively, be it in its existing form, or indirectly by a previous (or even subsequent) exchange, is *capital.* Suppose I have laid out all my money in wages and machinery, and the article I produce is just finished: in the interval, before I can sell these articles, realize the gain, and lay it out again in wages and tools, will it be said that I have *no capital?* Certainly not: I have the same capital as before, perhaps a larger one, but it is tied down, and is not disposable.' (p. 55.) (Notebook, p. 36.) 'At all times a very large part of the capital in a country lies idle. The annual product of a country never achieves in height what it could, if all resources were devoted to reproduction, if, in short, all the country's capital were in full employment. *If every commodity on the average remained unsold for a length of time equal to that required for its production, then it is clear that at any one time not more than a half of the productive capital of the country would in reality perform the function of capital. The employed half is a fluctuating portion,* composed of various elements; but the result would be that every producer would be capable of producing each year only half the supply of commodities which he could produce if he were sure of selling them at the moment of their completion.' (loc. cit. p. 55, 56.) 'This, or something similar, is, however, the usual state of a very great part of all capitalists in the world.' (p. 56.) 'The number of producers or vendors who turn over their capital in the very shortest time is very small. Few have so rapid a sale of their commodities that all goods which their own or borrowed capital can supply them can be *cleared out* as quickly as supplied. The majority do not have an *extent of business* at all adequate to the amount of capital they dispose of. It is true that in communities where industry and trade are practised with the greatest success, the contrivances of banking enable the owner of a capital greater than he can himself employ, to apply it productively and to derive a revenue from it. Still, even then, there is a great quantity of capital which remains *fixed* in the form of implements, machinery, buildings etc., whether only half employed or in complete employment: and every dealer keeps a *stock in trade,* to be ready for a possible sudden demand, although he may not be able to dispose of it for an indefinite period.' (p. 56.) '*This constant non-employment of a large part of capital* is the *price we pay for the division of labour. The purchase is worth what it costs; but the price is considerable.'* (56.) If I have 1,500 thalers in the shop and take in 10%, while 500 lie idle to ornament the shop, it is the same as if I invest 1,000 thalers at 7 1/2% ... 'In many trades there are a few dealers who sell articles of equal quality at a lower price than other dealers.

This is not a voluntary sacrifice of profits; from the consequent overflow of customers they expect to turn over their capital more rapidly, and to be the winners by keeping the whole of their capital in more constant employment, although on a given operation their gains are smaller.' (p. 56, 57.) 'It is questionable whether there are any dealers for whom one additional buyer is of no use; and for the great majority, this hypothesis altogether inapplicable. An additional customer is for most dealers equivalent to a growth of their productive capital. It enables them to transform a part of their capital, which lay idle (and perhaps would never have become productive in their hands until a customer had been found), into wages and instruments of production ... A country's aggregate product for the following year is hence increased; not through pure exchange, but by *calling into activity* a portion of the national capital which, had it not been for the exchange, would have remained unemployed for some time longer.' (57, 58.) 'The advantages gained from a *new customer* are, for the producer or dealer: (1) say, a part of his capital lies in the form of unsold goods, producing (during a longer or shorter time) nothing at all; then a part thereof is *called into greater activity* and *becomes more constantly productive.* (2) If the additional demand exceeds what can be supplied through liberation of capital existing as unsold goods, and if the dealer has additional resources (e.g. in government bonds), but not in his own trade, then he is enabled to obtain on a portion of these, no longer interest, but profit, and thus to gain the difference between the rate of interest and of profits. (3) If all his capital is employed in his own business and no part stored up as unsold goods, then he can conduct a surplus business with borrowed capital and gain the difference between interest and profit.' (59.)

Turnover of capital. ***Circulation process. Production process. Turnover. Capital circulates. Likewise fixed capital. Circulation costs. Circulation time and labour time. (Capitalist's free time.) (Transport costs)***

Now back to our subject.

The phases through which capital travels, which form one turnover of capital, begin conceptually with the transformation of money into the conditions of production. Now, however, that we begin not with capital in the process of becoming, but capital which has become, [we can see that] it travels through the following phases: (1) Creation of surplus value, or immediate production process. Its result, the product. (2) Bringing the product to market. Transformation of product into commodity. (3) (α) Entry of the commodity into ordinary circulation. Circulation of the commodity. Its result: transformation into money. This appears as the first moment of ordinary circulation. (β) Retransformation of money into the conditions of production: money circulation; in ordinary circulation, the circulation of commodities and the circulation of money always appear distributed among two different subjects. Capital circulates first as a commodity, then as money, and vice versa. (4) Renewal of the production process, which appears here as reproduction of the original capital, and production process of surplus capital.

The costs of circulation break down into costs of movement; costs to bring the product to market; the labour time required to effect the transformation from one state to the other; all of which actually come down to accounting operations and the time they cost (this is the foundation of a special, technical money trade). (Whether the latter costs are to be considered deductions from the surplus value or not will be seen later.)

If we examine this movement, we find that the circulation of capital, through the operation of exchanges, opens up at one point to release the product into general circulation, and to constitute itself out of the latter as equivalent in money. What happens to this product, which has in this way fallen out of the circulation of capital and into ordinary circulation, is here beside the point. On the other side, capital throws its form as money out of its circulation process again (partially, that is, in so far as it is not wages), or, after having realized itself as value in ordinary circulation and at the same time posited itself as the measure of its own realization, it then moves in the money form only as medium of circulation, and thus sucks into itself out of general circulation the commodities necessary for production (conditions of production). As commodity, capital throws itself out of its own circulation into general circulation; and, again as commodity, capital leaves general circulation and enters its own course, issuing into the production process. The circulation of capital thus contains a relation to general circulation, of which its own circulation forms a moment, while the latter likewise appears as posited by capital. This to be examined later.

The total production process of capital includes both the circulation process proper and the actual production process. These form the two great sections of its movement, which appears as the totality of these two processes. On one side, labour time, on the other, circulation time. And the whole of the movement appears as unity of labour time and circulation time, as unity of production and circulation. This unity itself is motion, process. Capital appears as this unity-in-process of production and circulation, a unity which can be regarded both as the totality of the process of its production, as well as the specific completion of *one* turnover of the capital, *one* movement returning into itself.

The condition, for capital, of circulation time is – besides labour time – only the same as the condition of production based on division of labour and exchange, in adequate form, in the highest form. The costs of circulation are costs of the division of labour and of exchange, which are necessarily found in every previous, pre-capitalist form of production resting on this basis.

As the subject predominant [*übergreifend*] over the different phases of this movement, as value sustaining and multiplying itself in it, as the subject of these metamorphoses proceeding in a circular course – as a spiral, as an expanding circle – capital is *circulating capital.* Circulating capital is therefore initially not a *particular* form of capital, but is rather *capital* itself, in a further developed aspect, as subject of the movement just described, which it, itself, is as its own realization process. In this respect, therefore, every capital is *circulating capital.* In simple circulation, circulation itself appears as the subject. One commodity is thrown out of it, another enters into it. But the same commodity is within it only fleetingly. Money itself, in so far as it ceases to be a medium of circulation and posits itself as independent value, withdraws from circulation. Capital, however, exists as the subject of circulation; circulation is posited as its own life’s course. But while capital thus, as the whole of circulation, is *circulating capital,* is the process of going from one phase into the other, it is at the same time, within each phase, posited in a specific aspect, restricted to a particular form, which is the negation of itself as the subject of the whole movement. Therefore, capital in each of its particular phases is the negation of itself as the subject of all the various metamorphoses.

Not-circulating capital. *Fixed capital,* actually *fixated* capital, fixated in one of the different particular aspects, phases, through which it must move. As long as it persists in one of these phases – [as long as] the phase itself does not appear as fluid transition – and each of them has its duration, [then] it is not circulating, [but] fixated. As long as it remains in the production process it is not capable of circulating; and it is virtually devalued. As long as it remains in circulation, it is not capable of producing, not capable of positing surplus value, not capable of engaging in the process as capital. As long as it cannot be brought to market, it is fixated as product. As long as it has to remain on the market, it is fixated as commodity. As long as it cannot be exchanged for conditions of production, it is fixated as money. Finally, if the conditions of production remain in their form as conditions and do not enter into the production process, it is again fixated and devalued. As the subject moving through all phases, as the moving unity, the unity-in-process of circulation and production, capital is *circulating* capital; capital as restricted into any of these phases, as posited in its *divisions,* is *fixated* capital, *tied-down* capital. As circulating capital it fixates itself, and as fixated capital it circulates. The distinction between *circulating capital* and *fixed capital* thus appears initially as a formal characteristic of capital, depending on whether it appears as the unity of the process or as one of its specific moments. The concept of *dormant capital,* capital lying fallow, can refer only to its barren existence in one of these aspects, and it is a condition of capital that part of it always lies fallow. This takes the visible form that a part of the national capital is always stuck in one of the phases through which capital has to move. *Money* itself, to the extent that it forms a particular part of the nation's capital, but always remains in the form of medium of circulation, i.e. never goes through the other phases, is therefore regarded by A. Smith as a subordinate form of fixed capital. [40] Capital can likewise lie fallow, be fixated in the form of money, of value withdrawn from circulation. During crises – *after* the moment of panic – during the standstill of industry, money is immobilized in the hands of bankers, billbrokers etc.; and, just as the stag cries out for fresh water, money cries out for a field of employment where it may be realized as capital.

Much confusion in political economy has been caused by this, that the aspects of circulating and fixed are initially nothing more than capital itself posited in the two aspects, first as the unity of the process, then as a particular one of its phases, itself in *distinction* to itself as unity – not as two particular kinds of capital, not capital of two particular kinds, but rather as different *characteristic forms of the same capital.* While some held fast to the aspect of a material product in which it was supposed to be circulating capital, others had no difficulty in pointing out the opposite aspect, and vice versa. Capital as the unity of circulation and production is at the same time the division between them, and a division whose aspects are separated in space and time, at that. In each moment it has an indifferent form towards the other. For the individual capital, the transition from one into the other appears as chance, as dependent on external, uncontrollable circumstances. *One and the same* capital therefore always appears in both states; this is expressed by the appearance of one part of it in one [phase], another in another; one part tied down, another part circulating; circulating, here, not in the sense that it is in the *circulatory phase proper* as opposed to the *production phase,* but rather in the sense that in the phase in which it finds itself it is in a *fluid* phase, a phase in-process, a phase in transition to the next phase; not stuck in one of them as such and hence delayed in its total process. For example: the industrialist uses only a part of the capital at his disposal (whether borrowed or owned is beside the point here, nor, if we consider capital as a whole, does it affect the economic process) in production, because another part requires a certain amount of time before it comes back out of circulation. The part moving [*prozessierend*] within production is then the circulating part; the part in circulation is the immobilized part. His total productivity is thereby restricted; the reproduced part restricted, hence also the part thrown on to the market restricted. Thus the merchant; a part of his capital is tied down as *stock in trade,* the other part moves. To be sure, sometimes one and sometimes another part is in this phase, as with the industrialist, but his total capital is always posited in both aspects. Then again, since this limit arising out of the nature of the realization process itself is not fixed, but changes with circumstances, and since capital can approach its adequate character as that which circulates, to a greater or lesser degree; since the decomposition into these two aspects, in which the realization process appears at the same time as the devaluation process, contradicts the tendency of capital towards maximum realization, it therefore invents contrivances to abbreviate the phase of fixity; and at the same time also, instead of the simultaneous coexistence of both states, *they alternate.* In one period the process appears as altogether fluid – the period of the maximum realization of capital; in another, a reaction to the first, the other moment asserts itself all the more forcibly – the period of the maximum devaluation of capital and congestion of the production process. The moments in which both aspects appear alongside one another themselves only form interludes between these violent transitions and turnings-over. It is extremely important to grasp these aspects of circulating and fixated capital as *specific characteristic forms* of capital generally, since a great many phenomena of the bourgeois economy – the period of the economic cycle, which is essentially different from the single turnover period of capital; the effect of new demand; even the effect of new gold- and silver-producing countries on general production – [would otherwise be] incomprehensible. It is futile to speak of the stimulus given by Australian gold or a newly discovered market. If it were not in the nature of capital to be never completely occupied, i.e. always partially *fixated,* devalued, unproductive, then no stimuli could drive it to greater production. At the same time, [note] the senseless contradictions into which the economists stray – even Ricardo – when they presuppose that capital is always fully occupied; hence explain an increase of production by referring exclusively to the creation of new capital. Every increase would then presuppose an earlier increase or growth of the productive forces.

These barriers to production based on capital are even more strongly inherent in the earlier modes of production, in so far as they rest on exchange. But they do not form a law of production pure and simple; [and,] as soon as exchange value no longer forms a barrier to material production, as soon as its barrier is rather posited by the total development of the individual, the whole story with its spasms and convulsions is left behind. As we saw earlier that money suspends the barriers of barter only by generalizing them – i.e. separating purchase and sale entirely – so shall we see later that *credit* likewise suspends these barriers to the realization of capital only by raising them to their most general form, positing one period of overproduction and one of underproduction as two periods.

The value which capital posits in one cycle, one revolution, one *turnover,* is

= to the value posited in the production process, i.e. = to the value reproduced + the new value. Whether we regard the turnover as completed at the point where the commodity is transformed into money, or at the point where the money is transformed back into conditions of production, the result, whether expressed in money or in conditions of production, is always absolutely equal to the value posited in the production process. We count the physical bringing of the product to market as = to 0; or, rather, we include it in the direct production process. The economic circulation of the product begins only when it is on the market as a commodity – only then does it circulate. We are dealing here only with the economic differences, aspects, moments of circulation; not with the physical conditions for bringing the finished product into the second phase, that of circulation as commodity; nor are we concerned with the technological process by which the raw material is transformed into product. The greater or lesser distance of the market from the producer etc. does not concern us here yet. What we want to determine here first of all is that the costs arising from the motion through the different economic moments as such, the *costs of circulation* as such, do not add anything to the value of the product, are not value-positing costs, regardless of how much labour they may involve. They are merely *deductions from the created* value. If, of two individuals, each one were the producer of his own product, but their labour rested on division of labour, so that they exchanged with each other, and the realization of their product depended on the satisfaction of their needs through this exchange, then obviously the time which this exchange would cost them, e.g. the mutual bargaining, calculating before closing the deal, would make not the slightest addition either to their products or to the latter's exchange values. If A were to argue that the exchange takes up so much time, then B would respond in kind. Each of them loses just as much time in the exchange as the other. The exchange time is their common time. If A demanded 10 thalers for the product – its equivalent – and 10 thalers for the time it costs him to get the 10 thalers from B, then the latter would declare him a candidate for the madhouse. This loss of time arises from the division of labour and the necessity of exchange. If A produced everything himself, then he would lose no part of his time in exchanging with B, or in transforming his product into money and the money into product again. The *costs of circulation* proper (and they achieve a significant independent development in the money trade) are not reducible to productive labour time. But they are also by nature restricted to the time it necessarily costs to transform the commodity into money and the money back into commodity; i.e. to the time it costs to transpose capital from one form into the other. B and A might now find that they could save time by inserting a third person C as middleman between them, who consumed his time in this *circulation process* – circumstances which would arise e.g. if there were enough exchangers, enough subjects of the circulation processes, so that the time needed by each pair of them alternately over a year = one year; each individual, say, had to spend 1/50 of a year alternately in circulation, and there are 50 of them, then 1 individual could spend his entire time in this occupation. For this individual, if only his necessary labour time were paid him, i.e. if he had to give up his entire time in exchange for the necessaries of life, then the reward which he would obtain would be wages. But if it amounted to his entire time, then the wage he would obtain would be an equivalent, objectified labour time. This individual then, would have added nothing to the value, but would, rather, have obtained a share of the surplus value belonging to capitalists A, B, etc. They would have gained, since, according to the presupposition, a lesser deduction from their surplus value would have taken place. (Capital is not a quantity simply, nor an operation simply; but both at the same time.) *Money* itself, to the extent that it consists of precious metals, or its production generally – e.g. in paper circulation – creates expense, to the extent that it also costs labour time, adds no value to the exchanged objects – to the exchange values; rather, its costs are a deduction from these values, a deduction which must be borne in proportional parts by the exchangers. The preciousness of the instrument of circulation, of the instrument of exchange, expresses only the *costs of exchange.* Instead of adding to value, they subtract from it. Gold money and silver money, e.g., are themselves values, *like others* (not in the sense of money), in so far as labour is objectified in them. But that these values serve as *medium of circulation* is a deduction from disposable wealth. The same relation holds for the production costs of the circulation of capital. This adds nothing to the values. The *costs of circulation* as such *do not posit value,* they are *costs of the realization of values* – deductions from them. *Circulation as a series of transformations,* in which capital posits itself; but, as regards value, circulation does not add to it, but posits it, rather, in the *form* of value. The potential value which is transformed into money through circulation is presupposed as a result of the production process. In so far as this series of processes takes place in time and involves costs, costs labour time, or objectified labour time, these *circulation costs* are deductions from the sum of value. When circulation costs are posited = 0, then the result of *one* turnover of capital, as regards value, = the value posited in the production process. That is, the value presupposed to circulation is the same as emerges from it. The most that can happen is that – owing to the circulation costs – a smaller value can come out than went in. In this respect, circulation time adds nothing to value; circulation time does not appear as value-positing time, the same as labour time. If production has created a commodity = to the value of £10, then circulation is necessary in order to equate this commodity to the £10, its value, which exists as money. The costs involved in this process, caused by this change of form, are a deduction from the value of the commodity. *The circulation of capital is the change of forms by means of which value passes through different phases.* The *time* which this process lasts or costs to bring about belongs among the *production costs of circulation, of the division of labour, of production based on exchange.*

This holds for *one turnover of capital,* i.e. for the single course of capital through this, its different moments. The process of capital as value has its point of departure in money and ends in money, but in a greater quantity of money. The difference is only quantitative. M–C–C–M has thus obtained a content. If we examine the cycle up to this point, we stand at the point of departure again. Capital has become money again. But it is now at the same time posited, it has now become a condition for this money that it becomes capital again, money which preserves and multiplies itself through the purchase of labour, by passing through the production process. Its form as money is posited as mere form; one of the many forms through which it moves in its metamorphosis. If we regard this point now not as a terminal point, but rather – as we must now regard it – as transition point, or new point of departure, itself posited by the production process as a vanishing terminal point and only a seeming point of departure, then it is clear that the retransformation of value, posited as money, into value-in-process, into value entering into the production process, can only proceed –

that the *renewal of the production process* can only take place – when the part of the circulation process which is distinct from the production process has been completed. The *second turnover* of capital – the retransformation of money into capital as such, or the renewal of the production process – depends on the time capital requires to complete its circulation; i.e. on its *circulation time,* the latter here as distinct from production time. But since we have seen that the total value created by capital (reproduced value as well as newly created), which is realized in circulation as such, is exclusively determined by the production process, it follows that the sum of values which can be created in a given period of time depends on the number of repetitions of the production process within this period. The repetition of the production process, however, is determined by circulation time, which is equal to the velocity of circulation. The more rapid the circulation, the shorter the circulation time, the more often can the same capital repeat the production process. Hence, in a specific cycle of turnovers of capital, the sum of values created by it (hence surplus values as well, for it posits necessary labour always merely as labour necessary for surplus labour) is *directly proportional to the labour time and inversely proportional to the circulation time.* In a given cycle, the total value (consequently also the sum of newly posited surplus values) = labour time multiplied by the number of turnovers of the capital. Or, the surplus value posited by capital now no longer appears as simply determined by the surplus labour appropriated by it in the production process, but rather [it is determined] by the coefficient of the production process; i.e. the number which expresses how often it is repeated in a given period of time. This coefficient, in turn, is determined by the circulation time required by the capital for one turnover. The sum of values (surplus values) is thus determined by the value posited in one turnover multiplied by the number of turnovers in a given period of time. One turnover of capital is = to the production time + the circulation time. If circulation time is presupposed as given, then the total time required for one turnover depends on the production time. If production time is given, the duration of the turnover depends on the circulation time. Hence, to the extent that circulation time determines the total mass of production time in a given period of time, and to the extent that the repetition of the production process, its renewal in a given period depends on the circulation time, to that extent is it itself a moment of production, or rather appears as a limit of production. This is the nature of capital, of production founded on capital, that circulation time becomes a determinant moment for labour time, for the creation of value. The independence of labour time is thereby negated, and the production process is itself posited as determined by exchange, so that immediate production is socially linked to it and dependent on this link – not only as a material moment, but also as an *economic* moment, a determinant, characteristic form. The maximum of circulation – the limit of the renewal of the production process through it – is obviously determined by the duration of production time during one turnover. Suppose the production process of a specific capital, i.e. the time it needs to reproduce its value and to posit surplus value, lasts 3 months. (Or, the time required to complete a quantity of product = to the total value of the producing capital + the surplus value.) Then this capital could under no circumstances renew the production or realization process more often than 4 times a year. The maximum turnover of this capital would be 4 turnovers per year; i.e. if no interruptions took place between the completion of one production phase and the renewal. The maximum number of turnovers would be = to the continuity of the production process, so that, as soon as the product was finished, new raw material would be worked up into product again. This continuity would extend not only to the continuity within a single production phase, but to the *continuity of these phases themselves.* But supposing now that this capital required one month of circulation time at the end of each phase – time to return to the form of conditions of production – then it could effect only 3 turnovers. In the first case the number of turnovers was = 1 phase × 4; or 12 months divided by 3. The maximum value-creation by capital in a given space of time is this space of time divide d by the duration of the production process (by production time). In the second case, the capital would effect only 3 turnovers a year; it would repeat the realization process only 3 times. The sum of its realization process would be, then, = 12/4 = 3. The divisor here is the total circulation time it requires: 4 months; or the circulation time required for one circulation phase, multiplied by the number of times this circulation time is contained in a year. In the first case, the number of turnovers = 12 months, a year, a given time, divided by the time of one production phase, or by the duration of production time itself; in the second case, it equals the same time divided by circulation time. The maximum realization of capital, as also the maximum continuity of the production process, is circulation time posited as = 0; i.e. then, the conditions under which capital produces, its restriction by circulation time, the necessity of going through the different phases of its metamorphosis, are suspended. It is the necessary tendency of capital to strive to equate circulation time to 0; i.e. to suspend itself, since it is capital itself alone which posits circulation time as a determinant moment of production time. It is the same as to suspend the necessity of exchange, of money, and of the division of labour resting on them, hence capital itself. If we ignore for a moment the transformation of surplus value into surplus capital, then a capital of 100 thalers, which produced a surplus value of 4% on the total capital in the production process, would, in the first case, reproduce itself 4 times and would at the end of the year have posited a surplus value of 16. At the end of the year, the capital would be = 116. It would be the same as if a capital of 400 had turned over once a year, likewise with a surplus value of 4%. As regards the total production of commodities and values, these would have quadrupled. In the other case, a capital of 100 thalers only created a surplus value of 12; the total capital at the end of the year = 112. As regards total production – in respect of either values or use values – the difference still more significant. In the first case e.g. a capital of 100 transformed 400 thalers of leather into boots, in the second only 300 thalers of leather.

The total realization of capital is hence determined by the duration of the production phase – which we posit as identical with labour time, for the moment – multiplied by the number of turnovers, or renewals of this production phase in a given period of time. If the turnovers were determined only by the duration of one production phase, then the total realization would be simply determined by the number of production phases contained in a given period of time; or, the turnovers would be absolutely determined by production time itself. This would be the *maximum of realization.* It is clear, therefore, that circulation time, regarded absolutely, is a deduction from the maximum of realization, is < absolute realization. It is therefore impossible for any velocity of circulation or any abbreviation of circulation to create a realization > that posited by the production phase itself. The maximum that the velocity of circulation could effect, if it rose to ∞, would be to posit circulation time = 0, i.e. to abolish itself.

It can therefore not be a positive, value-creating moment, since its abolition – circulation without circulation time – would be the maximum of realization; its negation = to the highest position of the productivity of capital. * The total productivity of capital is = the duration of one production phase multiplied by the number of times it is repeated in a certain period of time. But this number is determined by circulation time.

* The productivity of capital as capital is not the productive force which increases use values; but rather its capacity to create value; the degree to which it produces value.

Let us assume a capital of 100 turned over 4 times a year; posited the production process 4 times; then, if the surplus value = 5% each time, at the end of the year the surplus value created by the capital of 100 would = 20; then, for a capital of 400, which turned over once a year at the same percentage, would likewise = 20. So that a capital of 100, circulating 4 times, would give a gain of 20% a year, while a 4 times greater capital with a single turnover would give a profit of only 5%. (We shall see shortly, in more detail, that the surplus value is exactly the same.) It seems, therefore, that the magnitude of the capital can be replaced by the velocity of turnover, and the velocity of turnover by the magnitude of the capital. This is how it comes to appear as though circulation time were in itself productive. We must therefore clarify the matter by discussing this case.

Another question which arises: If the turnover of 100 thalers 4 times a year brings 5% each time, say, then at the beginning of the second turnover, the production process could be begun with 105 thalers, and the product would be 110 1/4; at the beginning of the third *turnover,* 110 1/4, of which the product would be 115 61/80 at the beginning of the fourth turnover, 115 61/80, and at its end, 121 881/1600. The number itself here is beside the point. The point is that, in the case of a capital of 400 which turns over once a year at 5%, the total gain can only be 20; while, by contrast, a 4 times smaller capital turning over 4 times at the same percentage makes a gain of 1 + 881/1600 more. In this way it appears as if the mere moment of turnover – repetition – i.e. a moment determined by circulation time, or rather a moment determined by *circulation,* not only realized value, but brought about an absolute growth of value. This also to be examined.

Circulation time only expresses the velocity of circulation; the velocity of circulation only the barrier to circulation. *Circulation without circulation time* – i.e. the transition of capital from one phase to the next at the speed of thought – would be the maximum, i.e. the identity of the renewal of the production process with its termination.

The act of exchange – and the economic operations through which circulation proceeds are reducible to a succession of acts of exchange – up to the point at which capital does not relate as commodity to money or as money to commodity, but as value to its specific use value, labour – the act of the exchange of value in one form for value in the other, money for commodity, commodity for money (and these are the moments of simple circulation), posits the value of one commodity in the other, and thus realizes it as exchange; or, also, posits the commodities as equivalents. The act of exchange is thus *value-positing* in so far as values are presupposed to it; it realizes the value-*character* of the subjects of exchange. [41] But an act which posits a commodity as *value,* or, what is the same, which posits another commodity as its *equivalent* – or, again the same, posits the *equivalence* of both commodities, obviously for its part adds nothing to value, as little as the sign ± increases or decreases the number coming after it. If I posit 4 as plus or as minus – through this operation, 4, independently of the sign, remains equal to itself, 4, becomes neither 3 nor 5. Likewise, if I exchange a lb. of cotton with an exchange value of 6d. for 6d., then it is posited as value; and it can equally be said that the 6d, are posited as value in the lb. of cotton; i.e. the labour time contained in the 6d. (here 6d. regarded as *value)* is now expressed in another materialization of the same amount of labour time. But, since through this act of exchange the lb. of cotton as well as the 6d. of copper are each posited at = to their value, it is impossible that through this exchange the value either of the cotton, or of the 6d. or of the sum of both values should increase quantitatively. As the positing of equivalents, exchange only changes the form; realizes the potentially existing values; realizes the prices, if you like. To posit equivalents, e.g. A and B as equivalents, cannot raise the value of A, for it is the act in which A is posited as = to its own value, hence not as unequal to it; unequal only where the form is concerned, in so far as it was previously not posited as value; it is at the same time the act by means of which the value of A is posited as = to the value of B, and the value of B as = the value of A. The sum of the values transposed in the exchange = value A + value B. Each remains = to its own value; hence their sum remains equal to the sum of their values. Exchange as the *positing of equivalents* cannot therefore by its nature increase the sum of values, nor the value of the commodities exchanged. (The fact that it is different with the exchange with labour arises because the use value of labour is itself *value-positing,* but is not directly connected with its exchange value.) And if a single operation of exchange cannot increase the value of the thing exchanged, neither can a sum of exchanges do it. * Whether I repeat an act which creates no value once or an infinite number of times, the repetition cannot change its nature. The repetition of a non-value-creating act can never become an act of value-creation. E.g. 1/4 expresses a specific proportion. If I transform this 1/4 into a decimal fraction, i.e. posit it = 0.25, then its form has been changed. This transformation leaves the value the same. Similarly, when I transform a commodity into the form of money, or money into the form of the commodity, then the value remains the same, but the form is changed. It is clear, therefore, that circulation – since it consists of a series of exchange operations with equivalents – cannot increase the value of circulating commodities. Therefore, if labour time is required to undertake this operation, i.e. if values have to be consumed, for all consumption of values reduces itself to the consumption of labour time or of objectified labour time, products; i.e. if circulation entails costs, and if circulation time costs labour time, then this is a deduction from, a relative suspension of the circulating values; their devaluation by the amount of the circulation costs. If one imagines two workers who exchange with each other, a fisherman and a hunter; then the time which both lose in exchanging would create neither fish nor game, but would be rather a deduction from the time in which both of them can create values, the one fish, the other hunt, objectify their labour time in a use value. If the fisherman wanted to get compensation for this loss from the hunter: demand more game, or give him fewer fish, then the latter would have the same right to compensation. The loss would be common to both of them. These costs of circulation, costs of exchange, could appear only as a deduction from the total production and value-creation of both of them. If they commissioned a third, C, with these exchanges, and thus lost no labour time directly, then each of them would have to cede a proportional share of his product to C. What they could gain thereby would only be a greater or lesser loss. But if they worked as joint proprietors, then no exchange would take place, only communal consumption. The costs of exchange would therefore vanish. Not the division of labour; but the division of labour founded on exchange. It is wrong, therefore, for J. St. Mill to regard the cost of circulation as *necessary price of the division of labour.* [42] It is the cost only of the [not-] spontaneous division of labour resting not on community of property, but on private property.

> * It is altogether necessary to make this clear; because the distribution of the surplus value among the capitals, the *calculation* of the total surplus value among the individual capitals – this *secondary* economic operation – gives rise to phenomena which are confused, in the ordinary economics books, with the primary ones.

Circulation costs as such, i.e. the consumption of labour time or of objectified labour time, of values, in connection with the operation of exchange and a series of exchange operations, are therefore a deduction either from the time employed on production, or from the values posited by production. They can never increase the value. They belong among the *faux frais de production,* and these *faux frais de production* belong to the inherent costs of production resting on capital. The merchant’s trade and still more the money trade proper – in so far as they do nothing but carry on the operations of circulation as such, e.g. the determination of prices (measurement of values and their calculation), these exchange operations generally, as a function which has gained independence through the division of labour, in so far as they represent this function of the total process of capital – represent merely the *faux frais de production* of capital. In so far as they reduce these *faux frais,* they add to production, not by creating value, but by reducing the negation of created values. If they operate purely as such a function, then they would always only represent the minimum of *faux frais de production.* If they enable the producers to create more values than they could without this division of labour, and, more precisely, so much more that a surplus remains after the payment of this function, then they have in fact increased production. Values are then increased, however, not because the operations of circulation have created value, but because they have absorbed less value than they would have done otherwise. But they are a necessary condition for capital's production.

The time a capitalist loses during exchange is as such not a deduction from labour time. He is a capitalist – i.e. representative of capital, personified capital, only by virtue of the fact that he relates to labour as alien labour, and appropriates and posits alien labour for himself. The costs of circulation therefore do not exist in so far as they *take away the capitalist's time.* His time is posited as *superfluous time: not-labour time, not-value-creating time,* although it is capital which realizes the created value. The fact that the worker must work surplus labour time is identical with the fact that the capitalist does not need to work, and his time is thus posited as not-labour time; that he does not work the *necessary* time, either. The worker must work surplus time in order to be allowed to objectify, to realize the labour time necessary for his reproduction. On the other side, therefore, the *capitalist's necessary labour time* is *free* time, not time required for direct subsistence. Since all *free time* is time for free development, the capitalist usurps the *free time* created by the workers for society, i.e. civilization, and Wade is again correct in this sense, in so far as he posits capital = civilization. [43]

Circulation time – to the extent that it takes up the time of the capitalist as such – concerns us here exactly as much as the time he spends with his mistress. If time is money, then from the standpoint of capital it is only alien labour time, which is of course in the most literal sense the capitalist's money. In regard to capital as such, circulation time can coincide with labour time only in so far as it interrupts the time during which capital can appropriate alien labour time, and it is clear that this relative devaluation of capital cannot add to its realization, but can only detract from it; or, in so far as circulation costs capital objectified alien labour time, values. (For example because it has to pay someone who takes over this function.) In both cases, circulation time is of interest only in so far as it is the suspension, the negation of alien labour time; either because it interrupts capital in the process of its appropriation; or because it forces it to consume a part of the created value, to consume it in order to accomplish the operations of circulation, i.e. to posit itself as capital. (Very much to be distinguished from the private consumption of the capitalist.) Circulation time is of interest only in its relation – as barrier, negation – to the production time of capital; this production time, however, is the time during which it appropriates alien labour, the alien labour time posited by it. To regard the time the capitalist spends in circulation as value-creating time or even surplus-value-creating time is to fall into the greatest confusion. Capital as such has no labour time apart from its production time. The capitalist absolutely does not concern us here except as capital. And he functions as such only in the total process we are examining. Otherwise, it could still be imagined that the *capitalist draws compensation for the time during which he does not earn money as another capitalist's wage labourer* – or that he *loses this time.* [Or] that it belongs together with the costs of production. The time which he employs or loses as capitalist is *lost time* altogether, sunk and unrecoverable from this standpoint. We will later look at the *capitalist's* so-called *labour time* as distinct from the worker's labour time, which former is alleged to form the basis of his *profits,* as a wage of its own type.

Nothing is more common than to bring transport etc., to the extent that they are connected with trade, into the pure circulation costs. In so far as trade brings a product to market, it gives it a new form. True, all it does is change the location. But the mode of the transformation does not concern us. It gives the product a new use value (and this holds right down to and including the retail grocer, who weighs, measures, wraps the product and thus gives it a form for consumption), and this new use value costs labour time, is therefore at the same time exchange value. Bringing to market is part of the production process itself. The product is a commodity, is in circulation only when it is on the market.

Circulation.* Storch. – *Metamorphosis of capital and metamorphosis of the commodity. – Capital's change of form and of substance. Different forms of capital. – Turnover in a given period. – Circulating capital as general character of capital.* – Year *the measure of turnovers of circulating capital.* Day *the measure of labour time

<'In every species of industry, the entrepreneurs become sellers of products, while the entire remainder of the nation and often even other nations are the buyers of these products ... the constant and incessantly repeated path which

circulating capital describes in order to take leave of the entrepreneur and in order to return to him in the first form is comparable to a circle; hence the name *circulant* given to this capital, and the use of the word circulation for its movement.' (p. [404,] 405.) (Storch. *Cours d'économie politique,* Paris, 1823, Vol. I, p. 405, Notebook, p. 34.) 'In the broad sense, circulation includes the motion of every commodity exchanged.' (p. 405, loc. cit.) 'Circulation proceeds by exchanges … from the instant of [the introduction of] currency, they [the commodities] are no longer exchanged but sold.' (p. 406, loc. cit.) 'For a commodity to be in circulation, it is sufficient that it be in supply … Wealth in circulation: *commodity.'* (p. 407, loc. cit.) 'Commerce only a part of circulation; the former includes only merchants' purchases and sales; the latter, those of all entrepreneurs and even of all … inhabitants.' (p. 408, loc. cit.) 'Only so long as the *costs* of circulation are indispensable to allow the *commodities to reach the consumers* is circulation real, and does *its value* increase the annual product. From the instant when it exceeds this degree, circulation is artificial and no longer contributes anything to the wealth of the nation.' (p. 409.) 'In recent years we saw examples of artificial circulation in St Petersburg in Russia. The slack state of foreign trade had led the merchants to realize their unemployed capitals in another way; no longer being able to employ them to bring in foreign commodities and to export domestic ones, they decided to take advantage of this by buying and reselling the commodities on hand. Monstrous quantities of sugar, coffee, hemp, iron etc. rapidly passed from one hand to the other, and a commodity often changed proprietors twenty times, without leaving the warehouse. This kind of circulation offers the dealers all manner of speculative opportunities; but while it enriches some, it ruins the others, and the nation's wealth gains nothing thereby. Likewise with the circulation of money … This kind of artificial circulation, based simply on a variation of prices, is termed *agiotage.'* (p. 410, 411.) 'Circulation brings no profit for society except in so far as it is indispensable to bring the commodity to the consumer. Every detour, delay, intermediate exchange which is not absolutely necessary for this purpose, or which does not contribute *to diminishing the circulation costs,* harms the national wealth, by uselessly raising the prices of commodities.' (p. 411.) 'Circulation is the more productive the more rapid it is; i.e. the less time it requires to relieve the entrepreneur of the finished product and bring it to market, and to bring the capital back to him in its first form.' (p. 411.) 'The entrepreneur can begin production again only after he has sold the completed product and has employed the price in purchasing new materials and new wages: hence, the more promptly circulation acts to bring about these two effects, the sooner is he in a position to begin his production anew, and the more profits does his capital bring in a given period of time.' (p. 412.) 'The nation whose capital circulates with a proper speed, so as to return several times a year to him who set it into motion, is in the same situation as the labourer of the happy climates who can raise three or four harvests in succession from the same soil in one year.' (p. 412, 413.) 'A slow circulation makes the objects of consumption more expensive (1) indirectly, through diminution of the mass of commodities which can exist; (2) directly because, as long as a product is in circulation, *its value progressively* increases by the interest of capital employed on its production; the slower the production, the more do these interest charges accumulate, which uselessly elevates the price of commodities.' 'Means for the abbreviation and acceleration of circulation: (1) the separating-out of a class of workers occupied exclusively with trade; (2) ease of transport; (3) currency; (4) credit.' (p. 413.)>

Simple circulation consisted of a great number of simultaneous or successive exchanges. Their unity, regarded as circulation, was actually present only from the observer's standpoint. (The exchange can be accidental, and it more or less has this character where it is restricted to the exchange of the excess product, and has not seized upon the totality of the production process.) In the circulation of capital we have a series of exchange operations, acts of exchange, each of which represents a qualitatively different moment towards the other, a moment in the reproduction and growth of capital. A system of exchanges, changes of substance, from the standpoint of value as such. Changes of form, from the standpoint of use value. The product relates to the commodity as use value to exchange value; thus the commodity to money. Here one series attains its peak. Money relates to the commodity into which it is retransformed as exchange value to use value; even more so, money to labour.

In so far as capital in every moment of the process is itself the possibility of going over into its other, next phase, and is thus the possibility of the whole process, which expresses capital's act of life, to that extent each of the moments appears potentially as capital – hence commodity capital, money capital – along with the value positing itself in the production process as capital. The commodity can represent money as long as it can transform itself into money, i.e. can buy wage labour (surplus labour); this in respect of the *formal side,* which emerges from the circulation of capital. On the material, physical side, it remains capital as long as it consists of raw material (proper or semi-fabricated), instrument, or necessaries for the workers. Each of these forms is potential capital. Money is in one respect the realized capital, capital as realized value. In this respect (regarded as a terminal point of circulation, where it then has to be regarded as a point of departure as well), it is capital, κατ᾽ ἐξοχήν. It is then especially capital again in regard to the part of the production process in which it exchanges itself for living labour. By contrast, in its exchange for the commodity (new purchase of raw material etc.) by the capitalist, it appears not as capital, but as medium of circulation; merely a vanishing mediation, through which the capitalist exchanges his product for the latter's original elements.

Circulation is not merely an external operation for capital. Just as it only becomes capital through the production process, in that value immortalizes and increases itself through that process, so does it become retransformed into the pure *form* of value – in which the traces of its becoming, as well as its specific presence in use value, have been extinguished —only through the first act of circulation; while the repetition of this act, i.e. the life process [of capital] is made possible only through the second act of circulation, which consists of the exchange of money for the conditions of production and forms the introduction to the act of production. Circulation therefore belongs *within* the concept of capital. Just as, originally, money or stockpiled labour appeared as presupposition *before* the exchange with free labour; the seeming independence of the objective moment of capital towards labour, however, was suspended, and objectified labour, become independent as value, appeared on all sides as the *product of alien labour,* the *alienated product* of labour itself; so does capital only now appear as presupposed to its circulation (capital as money was presupposed to its becoming capital; but capital as the result of value which has absorbed and assimilated living labour appeared as the point of departure not of circulation generally, but of the *circulation* of capital), so that it would exist independently and indifferently, even *without* this process. *However, the movement of the metamorphoses through which it must pass now appears as a condition of the production process* itself; just as much as its result. Capital, in its reality, therefore appears as a series of turnovers in a given *period.* It is no longer merely *one turnover,* one circulation; but rather the positing of turnovers; positing of the whole process. Its value-positing therefore appears as conditioned (and value is capital only as self-immortalizing and self-multiplying value) (1) *qualitatively;* in that it cannot renew the production phase without passing through the phases of circulation; (2) *quantitatively;* in that the mass of the values it posits depends on the number of its turnovers in a given period; (3) in that circulation time appears in both respects as limiting principle, as barrier of production time, and vice versa. Capital is therefore essentially *circulating capital.* While in the workshop of the production process capital appears as proprietor and master, in respect of circulation it appears as dependent and determined by social connections, which, from our present standpoint, make it enter into and figure in simple circulation alternately as C towards M and M towards C. But this circulation is a haze under which yet another whole world conceals itself, the world of the interconnections of capital, which binds this quality originating in circulation – in social intercourse – to itself, and robs it of the independence of self-sustaining property, as well as of its character. Two vistas into this presently still distant world have already opened up, at the two points at which the circulation of capital pushes the value posited and circulated by it in the form of the product out of its path, and, secondly, the point at which it pulls another product out of circulation into its own orbit; transforms this product itself into one of the moments of its presence *[Dasein].* At the second point it presupposes production; not its own immediate production; at the first point it may presuppose production, if its product is itself raw material for other production; or consumption if it has obtained the final form for consumption. This much is clear, that consumption need not enter into its circle *directly.* The actual circulation of capital, as we shall see later, is still circulation between dealers and dealers. The circulation between dealers and consumers, identical with the retail trade, is a second circle which does not fall within the immediate circulation sphere of capital. An orbit which it describes after the first is described, and simultaneously alongside it. *The simultaneity of the different orbits of capital,* like that of its different aspects, becomes clear only after many capitals are presupposed. Likewise, the course of human life consists of passing through different ages. But at the same time all ages exist side by side, distributed among different individuals.

Considering that the production process of capital is at the same time a technological process – production process absolutely – namely [the process] of the production of specific use values through specific labour, in short, in a manner determined by this aim itself; considering that the most fundamental of these production processes is that through which the body reproduces its necessary metabolism, i.e. creates the necessaries of life in the physiological sense; considering that this production process coincides with agriculture; and the latter also at the same time directly (as with cotton, flax etc.) or indirectly, through the animals it feeds (silk, wool, etc.), furnishes a large part of the raw materials for industry (actually all except those belonging to the extractive industries); considering that reproduction in agriculture in the temperate zone (the home of capital) is bound up with general terrestrial circulation; i.e. harvests are mostly *annual;* it follows that the *year* (except that it is figured differently for various productions) has been adopted as the general period of time by which the sum of the turnovers of capital is calculated and measured; just as the *natural working day* provided such a natural unit as measure of labour time. In the calculation of profit, and even more of interest, we consequently see the unity of circulation time and production time – capital – posited as such, and as its own measure. Capital itself as *in process* – hence, as accomplishing one turnover – is regarded as *working capital,* and the fruits, which it is supposed to yield, are calculated according to its working time – the total circulation time of one turnover. The mystification which thereby takes place lies in the nature of capital.

Fixed *(tied down) capital and circulating capital. – (Surplus. Proudhon. Bastiat.) – Mill. Anderson. Say. Quincey. Ramsay. – Difficulty with interest on interest. – Creating market through trade.* – Fixed and circulating capital. Ricardo. Money and capital. *Eternity of value. – Necessity of rapid or less rapid reproduction.*

Sismondi. ***Cherbuliez. Storch. – Capital's advance to labour***

Now, before we go more closely into the above-mentioned considerations, we want to see what distinctions the economists draw between *fixed capital* and *circulating capital.* We have already found, above, a new moment which enters with the calculation of profit as distinct from surplus value. Likewise already at this point a new moment has to arise between profit and interest. Surplus value in connection with *circulating capital* obviously appears as profit, in distinction to *interest* as the surplus value in connection with *fixed capital.* Profit and interest are both forms of the surplus value. Profit contained in the *price.* Hence, profit comes to an end and is realized as soon as capital has come to the point of its circulation where it is retransformed into money or passes from its form as commodity into the form of money. The striking ignorance on which Proudhon's polemic against interest rests, later. (Here one more time, so as not to forget, in regard to Proudhon: the surplus value which causes all Ricardians and anti-Ricardians so much worry is solved by this fearless thinker simply by mystifying it, 'all work leaves a surplus', 'I posit it as an axiom ... ' [44] The actual formulation to be looked up in the notebook. The fact that *work goes on beyond* necessary labour is transformed by Proudhon into a mystical quality of labour. This not to be explained by the mere growth of the productive force of labour; this may increase the products of a given labour time; but it cannot give a surplus value. It enters only in so far as it liberates surplus time, time for labour beyond the necessary. The only *extra-economic* fact in this is that the human being does not need his entire time for the production of the necessaries, that he has free time at his disposal above and beyond the labour time necessary for subsistence, and hence can also employ it for surplus labour. But this is in no way something mystical, since his necessaries are small to the same degree that his labour power is in a primitive state. But wage labour as such enters only where the development of the productive force has already advanced so far that a significant amount of time has become free; this liberation is here already a historic product. Proudhon's ignorance only equalled by Bastiat's decreasing rate of profit which is supposed to be the equivalent of a rising rate of wages. [45] Bastiat expresses this nonsense, borrowed from Carey, in a double way: first, the *rate* of profit falls (i.e. the proportion of surplus value in relation to the employed capital); secondly: prices decline, but value, i.e. the total sum of prices, rises, which is only another way of saying that the gross profit rises, not the rate of profit.)

Firstly, in the sense used by us above, of *fixated* capital, John St. Mill *(Essays on some Unsettled Questions of Political Econ.,* Lond., 1844, p. 55), [speaks of it] as tied-down, not disposable, not available capital. Stuck in one phase of its total circulation process. In this sense he says correctly, like Bailey in the above quotations, that a great part of the capital of a nation always lies idle.

'The difference between fixed and circulating capital is more apparent than real; e.g. gold is fixed capital; floating only in so far as it is consumed for gilding etc. Ships are fixed capital, although literally floating. Foreign railway shares are articles of commerce in our markets; so may our railways be in the markets of the world; and so far they are floating capital, on a par with gold.' (Anderson, *The Recent Commercial Distress etc.,* London, 1847, p. 4.) (Notebook I, 27.) [46]

According to Say: capital 'so much involved in one *kind of production* that it can no longer be diverted from it to be devoted to *another kind of production'.* [47] The identification of capital with a specific use value, use value for the production process. This quality of capital, *being tied down* as value to a particular use value – use value within production – is, however, an important aspect. This expresses more than the inability to circulate, which actually only says that fixed capital is the opposite of circulating capital.

In his *Logic of Political Economy* (p. 114) (Notebook X, 4), de Quincey says: *'Circulating capital,* in its normal idea, means *any agent whatever'* (beautiful logician) 'used productively which perishes in the very act of being used.' (According to this, coal would be *circulating capital,* and *oil,* but not cotton etc. It cannot be said that cotton perishes by being transformed into twist or calico, and such transformation certainly means using it productively); 'capital is *fixed* when the thing serves repeatedly always for the same operation, and by how much larger has been the range of iterations, by so much more intensely is the *tool, engine,* or *machinery* entitled to the denomination of fixed.' (p. 114.) (Notebook X, 4.) According to this, the circulating capital would die out, be consumed in the act of production; the fixed capital – which, for greater clarity, is characterized as *tool, engine,* or *machinery* (thus improvements incorporated in the soil are, for instance, excluded) – would serve repeatedly, always for the same operation. The distinction here concerns only technological differences in the act of production, not in the least the form-relation; circulating and fixed capital, in the differences here indicated, do have distinguishing features by means of which one particular agent is fixed and the other circulating, but neither of them any qualification which would entitle it to the *'denomination'* of *capital.*

According to Ramsay (IX, 84) [48] only 'the *approvisionnement* is *circulating capital,* because the capitalist must part with it immediately, and it *does not enter into the reproduction process at all,* but is rather exchanged directly for living labour, for consumption. All other capital (including raw material) remains in the possession of its owner or employer until the *produce is completed.'* (loc. cit. p. 21.) *'Circulating capital* consists only of subsistence and other necessaries advanced to the workman, previous to the completion of the produce of his labour.' (loc. cit. p. 23.) In regard to *approvisionnement* he is correct in so far as it is the only part of capital which circulates during the production phase itself, and which is in this respect circulating capital *par excellence.* In another respect it is false to say that fixed capital remains in the possession of its owner or employer 'until the produce is completed' and no longer than that. He consequently also later explains fixed capital as 'any portion of that labour (bestowed upon any commodity) *in a form* in which, though assisting to raise the future commodity, it does not *maintain labour*'. (But how many commodities do not maintain labour! I.e. do not belong among the workers' articles of consumption. These, according to Ramsay, are all *fixed capital.)*

(If the interest on £100 at the end of the first year or of the first 3 months is £5, then the capital at the end of the first year 105 or 100(1 + 0.05); at the end of the 4th year = $100(1 + 0.05)^4$ = £121. £55/100 and £1/1600 = £121 11s. 3/20 farthing or £121 11s. 0.15 farthing. Hence £1 11s. 3/20 farthing more than 20.)

(In the question posed above, assume that a first capital of 400 turns over only once a year, a second [capital of 100,] 4 times, both at 5%. In the first case the capital would make 5% once a year, = 20 on 400; in the second case 4 × 5%, likewise = 20 per year on 100. The velocity of turnover would substitute for the size of the capital; just as in simple money circulation 100,000 thalers which circulate 3 times a year = 300,000, while 3,000 which circulate 100 times = 300,000 also. But if the capital circulates 4 times a year, then it is *possible* that the surplus gain itself is ploughed into the capital for the second turnover, and turned over with it, producing thereby the difference of £1 11s. 0.15 farthing. But this difference in no way follows from the presupposition. All that is there is the *abstract* possibility. What would follow, rather, from the presupposition is that 3 months are required for the turnover of a capital of £100. E.g. therefore, if the month = 30 days, then for £105 – with the same turnover relation, with the same relation between the turnover time and the size of the capital – not 3 months are required, * but rather 105:x = 100:90; x = (90 × 105)/100 = 9450/100 = 94 5/10 days = 3 months, 4 1/2 days. With that, the first difficulty is completely solved.)

---

* Otherwise it could also be assumed, alternatively, that, if the production process is continuous, the obtained surplus is re-transformed into capital every 3 months.

(From the fact that a larger capital with a slower turnover does not create more surplus value than a smaller with a relatively more rapid turnover, it does not in the least automatically follow that a smaller capital turns over more rapidly than a larger. This is indeed the case in so far as the larger capital consists of more fixed capital and in so far as it has to search out more distant markets. The size of the market and the velocity of turnover are not necessarily inversely related. This occurs only as soon as the present, physical market is not the economic market; i.e. as the economic market becomes more and more distant from the place of production. To the extent, by the way, that [this relation] does not arise purely from the distinction between fixed and circulating capital, the moments which determine the circulation of different capitals cannot be at all developed yet here. An incidental remark: to the extent that trade posits new points of circulation, i.e. brings different countries into intercourse, discovers new markets etc., this is something entirely different from the mere costs of circulation required to carry out a given mass of exchange operations; it is the positing not of the operations of exchange, but of the exchange itself. Creation of markets. This point will have to be examined in particular before we have done with circulation.)

Now let us continue with our review of the opinions about ‘fixed’ and ‘circulating capital’. ‘Depending on whether *capital* is more or less *transitory, hence must be more or less frequently reproduced in a given time,* it is called *circulating or fixed capital.* Furthermore, capital circulates or returns to its employer in *very* unequal times; e.g. wheat which the farmer buys to sow is *relatively fixed* capital compared to the wheat a baker buys to make bread.’ (Ricardo VIII, 19.) Then he remarks also: ‘Different *proportions of fixed capital and circulating capital* in different trades; different *durability of fixed capital* itself.’ (Ricardo, loc. cit.) [49] ‘Two kinds of commerce can employ a capital of equal value, but which may be divided in a very different way as regards the fixed part and the circulating part. They may even employ an equal value of fixed capital and circulating capital, but the durability of the fixed capital may be very unequal. For example, one a steam engine of £10,000, the other, ships.’ (This out of Say’s translation of Ricardo, Vol. I, p. 29, 30.) The error from the outset is that, according to Ricardo, capital is supposed to be *‘more or less transitory’.* Capital as capital – *value* – is not transitory. But the use value in which the value is fixated, in which it exists, is ‘more or less transitory’, and must therefore be *‘more or less frequently reproduced* in a *given time’.* The difference between fixed capital and circulating capital is therefore reduced here to the *greater or lesser necessity for reproducing the given capital in a given time.* This is one distinction made by Ricardo. The other distinction concerns the different *degrees of durability,* or *different degrees of fixed capital,* i.e. *different degrees, relative durability of the relatively fixed.* So that fixed capital is itself more or less fixed. *The same capital* appears in the same business in the two different forms, the *particular modes of existence* of *fixed and circulating,* hence exists doubly. To be fixed or circulating appears as a *particular* aspect of capital apart from that of being capital. It must, however, proceed to this particularization. Finally, as for the third distinction, ‘that capital circulates or returns in very *unequal times’,* what Ricardo means by this, as his example of the baker and the farmer shows, is nothing more than the difference in the time during which capital is *fixed, tied up* in the *production phase* as distinct from the circulation phase, in different branches of business. Hence, *fixed capital* occurs here in the same way as we had it previously, as being fixated in each phase; except that the specifically longer or shorter fixation in the production phase, this phase in particular, is regarded as a peculiarity, particularity of capital [as value-] positing. Money attempted to posit itself as *imperishable value,* as eternal value, by relating negatively towards circulation, i.e. towards the exchange with real wealth, with transitory commodities, which, as Petty describes very prettily and very naïvely, dissolve in fleeting pleasures. [50] Capital posits the permanence of value (to a certain degree) by incarnating itself in fleeting commodities and taking on their form, but at the same time changing them just as constantly; alternates between its eternal form in money and its passing form in commodities; permanence is posited as the only thing it can be, a passing passage – process – life. But capital obtains this ability only by constantly sucking in living labour as its soul, vampire-like. The permanence – the duration of value in its form as capital – is posited only through reproduction, which is itself double, reproduction as commodity, reproduction as money, and unity of both these reproduction processes. In its reproduction as commodity, capital is fixated in a particular form of use value, and is thus not *general exchange value,* even less realized *value,* as it is supposed to be. The fact that it has posited itself as such in the act of reproduction, the production phase, is proved only through circulation. The greater or lesser perishability of the commodity in which value exists requires a slower or faster reproduction; i.e. repetition of the labour process. The *particular nature of use value,* in which the value exists, or which now appears as capital’s body, here appears as itself a *determinant* of the *form* and of the action of capital; as giving one capital a particular property as against another; as particularizing it. As we have already seen in several instances, nothing is therefore more erroneous than to assert [51] that the distinction between use value and exchange value, which falls outside the characteristic economic form in simple circulation, to the extent that it is *realized* there, falls outside it in general. We found, rather, that in the different stages of the development of economic relations, exchange value and use value were determined in different relations, and that this determination itself appeared as a different determination of value as such. Use value itself plays a role as an economic category. Where it plays this role is given by the development itself. Ricardo, e.g., who believes that the bourgeois economy deals only with exchange value, and is concerned with use value only exoterically, derives the most important determinations of exchange value precisely from use value, from the relation between the two of them: for instance, *ground rent, wage minimum, distinction between fixed capital and circulating capital,* to which he imputes precisely the most significant influence on the determination of prices (through the different reaction produced upon them by a rise or fall in the rate of wages); likewise in the relation of demand and supply etc. One and the same relation appears sometimes in the form of use value and sometimes in that of exchange value, but at different stages and with a different meaning. To use is to consume, whether for production or consumption. Exchange is the mediation of this act through a social process. Use can be posited as, and be, a mere consequence of exchange; then again, exchange can appear as merely a moment of use, etc. From the standpoint of capital (in circulation), exchange appears as the positing of its use value, while on the other side its use (in the act of production) appears as positing for exchange, as positing its exchange value. Likewise with production and consumption. In the bourgeois economy (as in every economy), they are posited in specific distinctions and specific unities. The point is to understand precisely these specific, distinguishing characteristics. Nothing is accomplished by the [assertions of] Mr Proudhon or of the social sentimentalists that they are *the same.*

The good thing in Ricardo's explanation is that it begins by emphasizing the moment of the necessity of *quicker or slower reproduction;* hence that the greater or lesser durability – consumption (in the sense of self-consumption), slower or more rapid – is regarded in connection with *capital* itself. Hence a relation of use value for *capital* itself. Sismondi by contrast immediately introduces a determinant initially exoteric to capital; *direct or indirect human consumption:* whether the article is a direct or an indirect necessary of life for the human consumer; he thereby joins this with the *quicker or slower consumption of the object itself.* The objects which serve directly as necessaries of life are more perishable, because designed to perish, than those which help to produce the necessaries of life. With the latter, their duration is their character; their transitoriness – fate. He says: 'Fixed, indirect capital is *slowly consumed,* in order to assist in consuming that which man destines for his use; circulating capital does not cease to be directly applied to the use of man ... Whenever a thing is consumed, it *never returns* for him who consumes it; while a thing consumed for reproduction is there for him at the same time.' (Sismondi VI.) He also presents the relation in such a way that: 'the *first transformation* of annual consumption into durable foundations, suitable for *increasing the productive powers of future labour – fixed capital;* this first labour always accomplished by labour, represented by a wage, exchanged for necessaries which the worker consumes during labour. *Fixed capital is consumed slowly'* (i.e. is slowly worn out). *Second transformation: 'Circulating capital* consists of *labour-seeds* (raw material) and of the *worker's consumption.'* (loc. cit.) [52] This is more concerned with the origin. Firstly the *transformation,* that fixed capital is itself only circulating capital which has assumed a stationary form, *fixated* circulating capital; second, the *destination:* the one destined to be consumed as means of production, the other as product; or the different mode of its *consumption,* determined by its role among the conditions of production in the production process. Cherbuliez simplifies the matter to the point where circulating capital is the *consumable, fixed capital* the not consumable part of capital. [53] (One you can eat, the other not. A very easy method of taking the thing.) In a quotation already given above [54] (29 in the Notebook), Storch vindicates for circulating capital generally the circulating nature of capital. He contradicts himself by saying: 'all fixed capital comes originally from a circulating capital, and needs continually to be maintained at the latter's expense' (hence comes out of circulation, or is itself circulating in its first moment and constantly renews itself *through* circulation; thus although *it* does not go *into circulation,* circulation goes into *it). As* for what Storch adds further: 'NO *fixed capital can give a revenue* EXCEPT *by means of a circulating capital'* (26a. Notebook), [55] we shall return to that later.

<'Reproductive consumption is not properly an expense, but only an *advance,* because it is reimbursed to its agent'; p. 54 in Storch's polemic against Say [56] (p. 5b. *Second* notebook on Storch). (The capitalist gives the worker a part of the latter's own surplus labour in the form of *advance,* as something for which he must reimburse the capitalist not merely with an equivalent, but with surplus labour as well.)>

(The formula for *computing compound interest* is: $S = c(1 + i)^n$. (S, the total magnitude of capital c after n years at an interest rate i.)

The formula for *computing an annuity* is:

$$x \text{ (the annuity)} = \frac{c(1+i)^n}{1 + (1+i) + (1+i)^2 + (1+i)^{n-1}}$$

Constant and variable capital

We divided capital above into *constant* and *variable value;* this is always correct as regards capital within the production phase, i.e. in its immediate realization process. How it is that capital itself, as presupposed value, can change its value as its reproduction costs rise or fall, or as a consequence of a decline in props also etc., evidently belongs to the section where capital is regarded as real capital, as the interaction of many capitals on one another, not here in its general concept.

Competition

<Because competition appears historically as the dissolution of compulsory guild membership, government regulation, internal tariffs and the like within a country, as the lifting of blockades, prohibitions, protection on the world market – because it appears historically, in short, as the negation of the limits and barriers peculiar to the stages of production preceding capital; because it was quite correctly, from the historical standpoint, designated and promoted by the Physiocrats as *laissez faire, laissez passer;* it has [therefore] never been examined even for this merely negative side, this, its merely historical side, and this has led at the same time to the even greater absurdity of regarding it as the collision of unfettered individuals who are determined only by their own interests – as the mutual repulsion and attraction of free individuals, and hence as the absolute mode of existence of free individuality in the sphere of consumption and of exchange. Nothing can be more mistaken. While free competition has dissolved the barriers of earlier relations and modes of

production, it is necessary to observe first of all that the things which were a barrier to it were the inherent limits of earlier modes of production, within which they spontaneously developed and moved. These limits became barriers only after the forces of production and the relations of intercourse had developed sufficiently to enable capital as such to emerge as the dominant principle of production. The limits which it tore down were barriers to its motion, its development and realization. It is by no means the case that it thereby suspended all limits, nor all barriers, but rather only the limits not corresponding to it, which were barriers to it. Within its own limits – however much they may appear as barriers from a higher standpoint, and are posited as such by its own historic development – it feels free, and free of barriers, i.e. as limited only by itself, only by its own conditions of life. Exactly as guild industry, in its heyday, found in the guild organization all the fullness of freedom it required, i.e. the relations of production corresponding to it. After all, it posited these out of itself, and developed them as *its* inherent conditions, and hence in no way as external and constricting barriers. The historical side of the negation of the guild system etc. by capital through free competition signifies nothing more than that capital, having become sufficiently strong, by means of the mode of intercourse adequate to itself, tore down the historic barriers which hindered and blocked the movement adequate to it. But competition is very far from having only this historic significance, or merely being *this negative* force. *Free competition* is the relation of capital to itself as another capital, i.e. the real conduct of capital as capital. The inner laws of capital – which appear merely as tendencies in the preliminary historic stages of its development – are for the first time posited as laws; production founded on capital for the first time posits itself in the forms adequate to it only in so far as and to the extent that free competition develops, for it is the free development of the mode of production founded on capital; the free development of its conditions and of itself as the process which constantly reproduces these conditions. It is not individuals who are set free by free competition; it is, rather, capital which is set free. As long as production resting on capital is the necessary, hence the fittest form for the development of the force of social production, the movement of individuals within the pure conditions of capital appears as their freedom; which is then also again dogmatically propounded as such through constant reflection back on the barriers torn down by free competition. Free competition is the real development of capital. By its means, what corresponds to the nature of capital is posited as external necessity for the individual capital; what corresponds to the concept of capital, is posited as external necessity for the mode of production founded on capital. The reciprocal compulsion which the capitals within it practice upon one another, on labour etc. (the competition among workers is only another form of the competition among capitals), is the *free,* at the same time the *real* development of wealth as capital. So much is this the case that the most profound economic thinkers, such as e.g. Ricardo, *presuppose* the absolute predominance of free competition [57] in order to be able to study and to formulate the adequate laws of capital – which appear at the same time as the vital tendencies governing over it. But free competition is the adequate form of the productive process of capital. The further it is developed, the purer the forms in which its motion appear. What Ricardo has thereby admitted, despite himself, is the *historic nature* of capital, and the limited character of free competition, which is just the free movement of capitals and nothing else, i.e. their movement within conditions which belong to no previous, dissolved stages, but are its own conditions. The predominance of capital is the presupposition of free competition, just as the despotism of the Roman Caesars was the presupposition of the free Roman 'private law'. As long as capital is weak, it still itself relies on the crutches of past modes of production, or of those which will pass with its rise. As soon as it feels strong, it throws away the crutches, and moves in accordance with its own laws. As soon as it begins to sense itself and become conscious of itself as a barrier to development, it seeks refuge in forms which, by restricting free competition, seem to make the rule of capital more perfect, but are at the same time the heralds of its dissolution and of the dissolution of the mode of production resting on it. Competition merely *expresses* as real, posits as an external necessity, that which lies within the nature of capital; competition is nothing more than the way in which the many capitals force the inherent determinants of capital upon one another and upon themselves. Hence not a single category of the bourgeois economy, not even the most basic, e.g. the determination of value, becomes real through free competition alone; i.e. through the real process of capital, which appears as the interaction of capitals and of all other relations of production and intercourse determined by capital. Hence, on the other side, the insipidity of the view that free competition is the ultimate development of human freedom; and that the negation of free competition = negation of individual freedom and of social production founded on individual freedom. It is nothing more than free development on a limited basis – the basis of the rule of capital. This kind of individual freedom is therefore at the same time the most complete suspension of all individual freedom, and the most complete subjugation of individuality under social conditions which assume the form of objective powers, even of overpowering objects – of things independent of the relations among individuals themselves. The analysis of what free competition really is, is the only rational reply to the middle-class [58] prophets who laud it to the skies or to the socialists who damn it to hell. The statement that, within free competition, the individuals, in following purely their private interest, realize the communal or rather the *general* interest means nothing other than that they collide with one another under the conditions of capitalist production, and hence that the impact between them is itself nothing more than the recreation of the conditions under which this interaction takes place. By the way, when the illusion about competition as the so-called absolute form of free individuality vanishes, this is evidence that the conditions of competition, i.e. of production founded on capital, are already felt and thought of as *barriers,* and hence already *are* such, and more and more become such. The assertion that free competition = the ultimate form of the development of the forces of production and hence of human freedom means nothing other than that middle-class rule is the culmination of world history – certainly an agreeable thought for the parvenus of the day before yesterday.>

Surplus value. Production time. Circulation time. **Turnover** *time*

<Before we go further with the review of opinions about fixed capital and circulating capital, we return for a moment to something developed earlier.

We assume for the time being that production time and labour time coincide. The case where interruptions take place within the production phase itself, owing to the technological process, will be looked at later.

Suppose the production phase of a capital equal to 60 working days; of which 40 are necessary labour time. Then, according to the law developed earlier, the surplus value, or the value newly posited by capital, i.e. appropriated alien labour time = 60 − 40; = 20. Let us call this surplus value (=20) S; the production phase – or the labour time employed in production – p. In a period of time which we shall call T – e.g. 360 days – the total value can never be greater than the number of production phases contained in, say, 360. The highest coefficient of S – i.e. the maximum of surplus value which capital can create on the given presuppositions – equals the number of times the creation of S is repeated in 360 days. The outer limit of this reproduction – the reproduction of capital, or rather, now, the reproduction of its production process – is determined by the relation of the production period to the total period of time in which the former can be repeated. If the given period = 360 days, and the duration of production = 60 days, then 360/60, or T/p, i.e. 6, is the coefficient indicating how many times p is contained in T, or how often, given its own inherent limits, the reproduction process of the capital can be repeated within 360 days. It goes without saying that the maximum of the creation of S, i.e. the positing of surplus value, is given by the number of processes in which S can be produced, in a given period of time. This relation is expressed by T/p. The quotient of T/p, or q, is the highest coefficient of S in the period of 360 days, in T generally. ST/p or Sq is the maximum of value. If $T/p = q$, then $T = pq$; i.e. the entire duration of T would be production time; the production phase, p, would be repeated as often as it is contained in T. The total value created by capital in a certain time would be = to the surplus labour it appropriates in one production phase, multiplied by the number of times this production phase is contained in the given time. Thus in the above example, = 20 × 360/60 = 20 × 6 = 120 days. q, i.e. T/p, would express the number of *turnovers* of the capital; but since $T = pq$, therefore $p = T/q$; i.e. the duration of one production phase would be equal to the total time divided by the number of turnovers. Thus one production phase of capital would be equal to one of its turnovers. Turnover time and production time would be completely identical; the number of turnovers therefore [would be] exclusively determined by the relation of one production phase to the total time.

However, on this assumption, circulation time is posited as = 0. Yet circulation time has a definite magnitude, which can never become = 0. Now assume additionally that there are 30 days for circulation for every 60 days of production time; call this circulation time added to p, c. In this case, one turnover of capital, i.e. the total time it requires before it can repeat the realization process – the positing of surplus value – would be = 30 + 60 = 90 days ($= p + c$) (1R (turnover) $= p + c$). One turnover of 90 days can be repeated in 360 days only 360/90 times, i.e. 4 times. The surplus value of 20 could therefore be posited only 4 times; 20 × 4 = 80. In 60 days the capital produces 20 surplus days; but it has to circulate for 30 days; i.e. during these 30 days it can posit no surplus labour, no surplus value. This is the same for it (as regards the result) as if it had posited a surplus value of only 20 in the period of 90 days. While previously the number of turnovers was determined by T/p, it is now determined by $T/(p + c)$ or T/R; the maximum of value was $ST/(p + c)$; (20 × (300/(60 + 30)) = 20 × (360/90) = 20 × 4 = 80). The number of turnovers hence = the total time divided by the sum of production time and circulation time, and the total value = S multiplied by the number of turnovers. But this formulation does not yet suffice for us to express the relations of surplus value, production time and circulation time.

The maximum of value creation contained in the formula ST/p; value creation restricted by circulation, $ST/(p + c)$ (or ST/R); when we subtract the second amount from the first, then

$$\frac{ST}{p} - \frac{ST}{p + c} =$$

$$\frac{ST(p + c) - STp}{p(p + c)} = \frac{STp + STc - STp}{p(p + c)} = \frac{STc}{p(p + c)}$$

As difference we then obtain $STc / p(p + c)$ or $ST/p \times c/(p + c)$; $ST/(p + c)$ or S', as we may call this value in the second form, $S' = ST/p - (ST/p \times c/(p + c))$. But before we develop this formula further, there are still others to be introduced.

If we call the quotient of $T/(p + c)$ q', then q' expresses the number of times $R = (p + c)$ is contained in T, the number of turnovers. $T/(p + c) = q'$; hence $T = pq' + cq'$. pq' then expresses the total production time and cq' the total circulation time.

Let us call total circulation time C (hence $cq' = C$). ($T(360) = 4 \times 60\ (240) + 4 \times 30\ (120)$.) With our presupposition, $q' = 4$, $C = cq' = 4c$; 4 being = to the number of turnovers. We saw previously that the maximum of value-creation = ST/p; but in this case T was posited as = to production time. But the real production time is now $T - q$; as indeed follows from the equation. $T = pq'$ (total production time) + cq' (total circulation time, or C). Hence $T - C = cq'$. Hence $S(T - C) / p$ the maximum value creation. Because production time not 360 days, but $360 - cq'$, i.e. – 4 × 30 [=] 120; hence $20((360 - 120)/60)$; $(20 \times 240)/60 = 80$.

Now, finally, as regards the formula

$S' = ST/p - (ST/p \times c/(c + p)) = (360 \times 20)/60 - 20(360/60 \times 30/(30 + 60))$

$= 120 - (120 \times 30/90) = 6 \times 20 - (6 \times 20 \times 3/9)$

$= 20 \times 6 - (20 \times 6 \times 1/3)$ or

$= 120 - (120 \times 1/3) = 120 - 40 = 80$,

it signifies that value is equal to the maximum of value, i.e. to value determined only by the relation of production time to total time, minus the number which expresses how often the circulation time is contained in this maximum, plus $c/(c + p) = c/R$; c/R expresses the relation of circulation time to one turnover of capital. If we multiply numerator and denominator by q' then $cq' / (c + p)q' = C/T$; $c/(c + p) = 30/(30 + 60) = 1/3$. $c/(c + p)$ or 1/3 expresses the relation of circulation time to total time, for 360/3 = 120. The turnover $(c + p)$ is contained in C, $c/(c + p)$ or 1/3 times (or c/T times), and this number is the maximum itself multiplied by the number of times a turnover is contained in c, in the circulation time added to one turnover, or divided by the number which expresses how often c is contained in $c + p$ or C in T. If $c =$

0, then S' would be ST/p and would be at its maximum. S' becomes smaller in the same degree as C grows, is inversely related to it, for the factor $c/(c + p)$ and ST/p grows to the same degree. The number to be subtracted [from] the maximum value, $ST/p \times c/(c + p)$ or $ST/p \times c/R$.

We have, then, the three equations: (1) $S' = ST/(p + c) = ST/R$; (2) $S' = S(T - C) / p$; (3) $S' = ST/p - (ST/p \times c/(c + p)) = S[T/p - (T/p \times c/(c + p))]$.

Hence: $S:S' = ST/p: S(T - C) / p$; or $S:S' = T:(T - C)$. The maximum of value is to the real value as a given period of time is to this period of time minus total circulation time. Or, as well, $S:S' = pq':(pq' - q'c)$, i.e. $= p:(p - c)$.

On (3) $S' = ST/p - (ST/p \times c/(c + p)) = S[T/p - (T/p \times c/(c + p))]$ or, since $T/p = q$,

$S' = S\ (q - q \cdot c/(c + p)) = S(q - qc/R)$. The total surplus value, therefore, = to the surplus value posited in one production phase, whose coefficient is the number of times the production time is contained in the total time minus the number of times the circulation time of one turnover is contained in this latter number.

$S(q - qc/R) = Sq(1 - 1c/R) = Sq((R - c)/R) = Sqp/R = ST/(p + c)$, which is the first equation. Thus equation 3 means ... *equation* 1: the total surplus value equals the surplus value of one production phase multiplied by the total time, divided by turnover time or multiplied by the number of times the sum of production time and circulation time is contained in total time.

Equation 2: The total value equals surplus value multiplied by total time minus the total circulation time, divided by the duration of one production phase.>

Competition

(The fundamental law in competition, as distinct from that advanced about value and surplus value, is that it is determined not by the labour contained in it, or by the labour time in which it is produced, but rather by the labour time in which it can be produced, or, the labour time necessary for reproduction. By this means, the individual capital is in reality only placed within the conditions of capital as such, although it seems as if the original law were overturned.

Necessary labour time as determined by the movement of capital itself; but only in this way is it posited. This is the fundamental law of competition. Demand, supply, price (production costs) are further specific forms; price as market price; or general price. Then the positing of a general rate of profit. As a consequence of the market price, the capitals then distribute themselves among different branches. Reduction of production costs etc. In short, here all determinants appear in a position which is the *inverse* of their position in capital in general. There price determined by labour, here labour determined by price etc. etc. The influence of individual capitals on one another has the effect precisely that they must conduct themselves as *capital*; the seemingly independent influence of the individuals, and their chaotic collisions, are precisely the positing of their general law. Market here obtains yet another significance. The influence of capitals as individuals on each other thus becomes precisely their positing as general beings, and the suspension of the seeming independence and independent survival of the individuals. This suspension takes place even more in credit. And the most extreme form to which the suspension proceeds, which is however at the same time the *ultimate positing* of capital in the form adequate to it – is joint-stock capital.) (Demand, supply, price, production costs, contradiction of profit and interest, different relations of exchange value and use value, consumption and production.)

Surplus value. Production time. Circulation time. **Turnover time.** ***Part of capital in production time, part in circulation time. – Circulation time. – Surplus value and production phase. Number of reproductions of capital = number of turnovers. – Total surplus value etc.***

We have seen, then, that the surplus value a capital can posit in a given period of time is determined by the number of times the realization process can be repeated, or the capital can be reproduced in a given period of time; and that the number of these reproductions is determined by the relation of the duration of the production phase not to the total period of time, but rather to this total time minus circulation time. Circulation time thus appears as time during which the ability of capital to reproduce itself, and hence to reproduce surplus value, is suspended. Its productivity – i.e. its creation of surplus values – is therefore inversely related to circulation time, and would reach its maximum if the latter declined to 0. Circulation is an inescapable condition for capital, a condition posited by its own nature, since circulation is the passing of capital through the various conceptually determined moments of its necessary metamorphosis – its life process. In so far as it costs time for capital to run through this course, in this time capital cannot *increase* its value, because it is not-production time, time in which it does *not* appropriate living labour. Hence this circulation time can never increase the value created by capital, but can only posit *not-value-positing* time, hence appear as barrier to the increase of value, in the same relation as it stands towards labour time. This circulation time cannot be counted as part of value-creating time, for the latter is labour time which objectifies itself in value, and nothing else. It does not belong to the production costs of value, nor to the production costs of capital; but it is a condition which makes its self-reproduction more difficult. The obstacles which capital encounters in the path of its realization – i.e. its appropriation of living labour – do not, of course, form a moment of its realization, of its value-creation. Hence it is ridiculous to take *production costs* here in the original sense. Or we have to distinguish production costs as a particular form from the labour time which objectifies itself in value (as we must distinguish profit from surplus value). But even then, circulation time does not belong among capital's production costs in the same sense as wages etc.; but rather it is an item which comes into consideration as part of the capitalists' settling of accounts with one another, because they distribute the surplus value among themselves according to certain general proportions. Circulation time is not time during which capital creates value, but rather during which it realizes the value created in the production process. It does not increase its quantity, but rather transposes it into another form, from the form of product into that of commodity, from commodity to that of money etc.; the fact that the price which previously existed ideally in the commodity is now really posited, that it is now really exchanged for its price – money – does not, of course, increase this price. Thus circulation time appears as time which does not determine the price; and the number of turnovers, in so far as it is determined by circulation time, appears not in such a way that capital brings in a new value-determining element, an element proper to it, *sui generis*, as distinct from labour; but rather as a limiting, negative principle. The necessary tendency of capital is therefore *circulation without circulation time,* and this tendency is the fundamental determinant of credit and of capital's credit contrivances. At the same time, credit is then also a form in which capital tries to posit itself as distinct from the individual capitals, or the individual capital [tries to posit] itself as capital as distinct from its quantitative barrier. But the highest result it achieves in this line is, on one side, *fictitious capital;* on the other side, credit only appears as a new element of *concentration*, of the destruction of capitals by individual, centralizing capitals. Circulation time is in one respect objectified in *money*. Attempt by credit to posit money as a merely formal moment; so that it mediates the formal transformation without itself being *capital*, i.e. value. This is one form, of circulation without circulation time. Money is itself a product of circulation. It will be shown how capital, in credit, creates new products of circulation. But if the striving of capital in one direction is *circulation without circulation time*, it strives in the other direction to give *circulation time value*, the value of *production time,* in the various organs which mediate the process of circulation time and of circulation; to posit them all as money, and, more broadly, as capital. This is another side of credit. All this springs from the same source. All the requirements of circulation, money, transformation of commodity into money, transformation of money into commodity etc. – although they take on different and seemingly quite heterogeneous forms, are all derived from *circulation time*. The machinery for abbreviating it is itself a part of it. *Circulation time* is that part of capital which may be regarded as the time it takes to perform its specific motion as capital, as distinct from production time, in which it reproduces itself; and in which it lives not as finished capital which must merely pass through formal metamorphoses, but as capital-in-process, creative capital, sucking its living soul out of labour.

The contradiction of labour time and circulation time contains the entire doctrine of credit, to the extent, namely, that the history of currency etc. enters here. Now, of course, later, where circulation time is not the only deduction from possible production time, there also appear real costs of circulation, i.e. values which have already been really posited must be spent on circulation. But these are all in fact only costs – deductions from already created surplus values – which capital undertakes in order to increase the sum of surplus values possible e.g. in a year, i.e. to increase the proportion of production time out of a given total time – i.e. to abbreviate circulation time. Of course, in practice, production time does not really appear interrupted by circulation time (except in crises and depressions of trade). But this is only because every capital is divided into parts, one part in the production phase, the other in the circulation phase. Thus, for example, it is not the entire capital that is active (depending on the relation of circulation time to production time), but only 1/3, 1/*x* of it; the other is engaged in circulation. Or the matter can further take the form that a given capital doubles (through credit, e.g.). For this capital – the original capital – it is then the same as if circulation time did not exist at all. But then the capital borrowed by it is in this plight. And if ownership is disregarded, again exactly the same as if one capital were divided in two. Instead of *a* dividing into two and *b* dividing into two, *a* absorbs *b* and divides into *a* and *b*. Illusions about this process frequent among credit-mystics [59] (who are rarely creditors, but rather debtors).

We already pointed out above that the double and contradictory condition of capital, the continuity of production and the necessity of circulation time, and also the continuity of circulation (not circulation time) and the necessity of production time, can be mediated only by capital dividing itself into parts, of which one *circulates as finished* product, and the other *reproduces itself in the production process.* These parts alternate; when one part returns into phase *P* (production process), the other departs. This process takes place daily, as well as at longer intervals (dimensions of time). The whole capital and the total value are reproduced as soon as both parts have passed through the production process and circulation process, or as soon as the second part enters anew into circulation. The point of departure is thereby the terminal point. The turnover therefore depends on the size of the capital, or rather, here, still on the *total sum* of these two parts. Only when the total sum is reproduced has the entire *turnover* been completed; otherwise only 1/2, 1/3, 1/*x*, depending on the relation of the constantly circulating part.

It has further been emphasized that each part can be regarded as fixed or as circulating in contrast to the other, and that they really relate to each other in this alternating way. The simultaneity of the process of capital in different phases of the process is possible only through its division and break-up into parts, each of which is capital, but capital in a different aspect. This change of form and matter is like that in the organic body. If one says e.g. the body reproduces itself in 24 hours, this does not mean it does it all at once, but rather the shedding in one form and renewal in the other is distributed, takes place simultaneously. Incidentally, in the body the skeleton is the fixed capital; it does not renew itself in the same period of time as flesh, blood. There are different degrees of speed of consumption (self-consumption) and hence of reproduction. (Here, then, already *transition to* many capitals.) The important thing here above all is to examine capital as such for itself first of all; since the aspects being developed here are those which make value in general into capital; which constitute the specific distinguishing characteristics of capital as such.

Before we go further, let us call attention once more to the important point that circulation time – i.e. the time during which capital is separated from the process in which it absorbs labour, i.e. the labour time of capital as capital – is only the transposition of *previously created* value from one form into the other, but not a *value-creating*, value-*increasing* element. The transformation of a value of 4 working days existing in the form of twist into the form of 4 working days existing as money, or of a symbol recognized as the representative of 4 working days as such, 4 working days in general, transposes the *previously created* and *measured* value from one form into another, but that value is not increased. The exchange of equivalents leaves the working days *after* the exchange just as they were *before, qua* amounts of value. If one thinks of one capital, or one thinks of the various capitals of a country as one capital (national capital) as distinct from that of other countries, then it is clear that the time during which this capital does not act as productive capital, i.e. posits no surplus value, is a deduction from the realization time available to this capital. In this abstract conception, still without any regard to the costs of circulation itself, it appears as the negation not of the really posited realization time, but of the *possible* realization time, i.e. possible if circulation time = 0. It is clear, now, that the national capital cannot regard the time during which it does not multiply itself as time in which it does multiply itself, no more than e.g.

an isolated peasant can regard the time during which he can neither harvest nor sow, during which his labour generally is interrupted, as time which makes him rich. The fact that capital regards itself, and necessarily so, as productive and fruit-bearing independently of labour, of the absorption of labour, assumes itself as fertile at all times, and calculates its circulation time as value-creating time – as production cost – is quite another thing. In this way one can see what is wrong when e.g. Ramsay says: ‘the use of fixed capital modifies to a considerable extent the principle that value depends on quantity of labour. For some commodities on which the same quantity of labour has been expended require very different periods before they are fit for consumption. But as during this time the capital brings no return, *in order that the employment in question should not be less lucrative than others in which the produce is sooner ready for use,* it is necessary that the commodity, when at last brought to market, should be increased in value *by all the amount of profit withheld.’* (This already assumes that capital as such regularly brings profit, like a healthy tree brings fruit.) *‘This shews ... how capital may regulate value independently of labour.’* [60] E.g. wine in the cellar. (Ramsay, IX, 84.) Here as if circulation time as well as labour time – or on the same level with it – produced *value.* Capital, of course, contains both moments in itself. (1) *Labour time* as a value-creating moment. (2) *Circulation time* as a moment which restricts labour time and thus restricts the total value creation of capital; as necessary, because value, or capital, as an immediate result of the production process, is indeed *value,* but value not posited in its adequate form. The time which is required for these changes of form – i.e. which elapses between production and reproduction – is time which devalues capital. Thus, like *continuity,* so is the *interruption* of continuity contained in the character of capital as circulating, in process.

The economists who correctly characterize circulation, the revolution which capital must go through to fire itself up for new production, as a series of exchanges thereby admit that this circulation time is not time which increases the quantity of values – hence it cannot be time which posits new values – because a series of exchanges, no matter how many exchanges it may include, and how much time the completion of these operations may cost, is merely the exchange of equivalents. The positing of values – the extremes of the mediation

– as equivalents naturally cannot posit them as non-equivalents. Regarded quantitatively, they can have neither increased nor diminished through the exchange.

The surplus value of a production phase is determined by the surplus labour set in motion (appropriated) by capital during it; the sum of the surplus values a capital can create in a given period of time is determined by the repetition of the production phase in this period of time; or by the *turnover* of capital. The turnover, however, equals the duration of the production phase plus the duration of circulation, equals the sum of circulation time and production time. The turnover approaches production time as circulation time diminishes, i.e. the time which elapses between capital's departure from production and its return to it.

Surplus value is in fact determined by the labour time objectified during one production phase. The more frequent the reproduction of capital, the more often does the production of surplus value take place. The number of reproductions = the number of turnovers. Hence the total surplus value = $S \times nR$ (if n is the number of turnovers). $S' = S \times nR;$ hence $S = S'/nR$. If the production time required by a capital of £100 in a certain branch of industry equals 3 months, then it could turn over 4 times a year, and if the S-value created each time = 5, then the total surplus value = 5 (the S created in one production phase) × 4 (the number of turnovers, determined by the relation of production time to the year) = 20. But if circulation time = e.g. 1/4 of production time, then 1 turnover would = 3 + 1 months, equals 4 months, and the capital of 100 could turn over only 3 times a year = 15. Hence, although the capital posits an S-value of £5 in 3 months, it is the same for it as if it posited a value of 5 in only 4 months, because it can only posit 5 × 3 per year. It is the same for it as if it produced an S of 5 every 4 months; hence produced only 15/4 or 3 3/4 in 3 months, and in the one circulation month, 1 1/4. In so far as turnover is distinct from the duration posited by the conditions of production, it is = to circulation time. The latter, however, is not determined by labour time. In this way the sum of surplus values which capital posits in a given period of time appears determined not simply by labour time, but by labour time as well as circulation time, in the relations indicated above. But, as shown above, the determination which capital here brings into the positing of value is *negative,* *limiting.*

If e.g. a capital of £100 needs 3 months for production, say 90 days, then, if circulation time = 0, the capital could turn over 4 times a year; and it would be *entirely* active as capital the whole time, i.e. positing surplus labour, multiplying its value. If 80 of the 90 days represented necessary labour, then 10, surplus labour. Now posit that circulation time amounts to 33 1/3% of production time, or 1/3 of it. Hence 1 month for every 3. Circulation time then = 90/3; a third of production time = 30 days, $c = 1/3\ p$; ($c = p/3$). Well. The question is, what part of the capital can now continuously be occupied in production (during the whole year)? If the capital of 100 had worked 90 days, and then circulated as a product of 105 for one month, then during this month it could employ no labour at all. (The 90 working days can of course equal 3, 4, 5, x times 90, depending on the number of workers employed during the 90 days. These would be = to only 90 days if only 1 worker were employed. But this is beside the point for now.) (In all these calculations it is presupposed that the surplus value is not in turn capitalized, but that capital rather continues to work with the same number of workers; but at the same time as the surplus is realized, the entire capital is only then realized as money.) That is, during one month the capital could not be employed at all. (The capital of 100 employs e.g. 5 workers continuously; this contains their surplus labour, and the product which is circulated is never the original capital, but rather that which has absorbed this surplus labour and hence has a surplus value. Hence the circulation of a capital of 100 actually means e.g. circulation of the capital of 105; i.e. of capital together with the profit posited in one act of production. But this error irrelevant here, particularly in the above question.)

(Posit that at the end of 3 months £100 worth of twist have been produced.) Now it will be 1 month before the money comes in and I can begin production again. Now, in order to set the same number of workers to work during the I month while the capital is circulating, I would have to have a surplus capital of £33 1/3; for if £100 set a given quantity of labour in motion for 3 months, then 1/3 of £100 would set it in motion for 1 month. At the end of the fourth month, the capital of 100 would return to the production phase, and that of 33 1/3 would enter the circulation phase. The latter would require 1/3 of a month for circulation, given the same relations; would hence return into production after

10 days. The first capital could enter into circulation again only at the end of the seventh month. The second, which entered into circulation at the beginning of the fifth month, would have returned say on the 10th of the fifth month, would re-enter circulation on the 10th of the sixth month and would return on the 20th of the sixth month, to re-enter circulation on the 20th of the seventh month; at the end of the seventh month it would be back again, at which time the first capital would just be beginning its course again at the same moment when the second was returning. Beginning of the eighth month, and return on the etc. Beginning of the ninth etc. In a word: if the capital were 1/3 larger – just the amount the circulation time adds up to – then it could continuously employ the same number of workers. Or, alternately, it could continuously remain in the production phase if it continuously employed 1/3 less labour. If the capitalist began with a capital of only 75, then production would finish at the end of the third month; then the capital would circulate for one month; but during this month he could continue production because he would have retained a capital of 25, and, if he needs 75 to set a given mass of labour in motion during 3 months, he needs 25 to set the same in motion for 1 month. He would continuously have the same number of workers at work. Each of his commodities requires 1/12 of a year before it is sold.

If he always needs 1/3 of the production time to sell his commodities, then etc. This matter must be reducible to a very simple equation, to which we shall return later. It does not actually belong here. But the question is important because of the credit questions later. This much is clear, however. Call production time pt, circulation time ct. Capital, C. C cannot be in its production phase and its circulation phase at the same time. If it is to continue to produce while it circulates, then it must break into two parts, of which one in the production phase, while the other in the circulation phase, and the continuity of the process is maintained by part a being posited in the former aspect, part b in the latter. Let the portion which is always in production be x; then $x = C - b$ (let b be the part of the capital always in circulation). $C = b + x$. If ct, circulation time, were = 0, then b likewise would be = 0, and $x = C$. b (the part of the capital in circulation):C (the total capital) = ct (circulation time):pt (production time); $b:C = ct:pt$; i.e. the relation of circulation time to production time is the relation of the part of capital in circulation to the total capital.

If a capital of 100 at a profit of 5% turns over every 4 months, so that there is 1 month of circulation time for every 3 months of production time, then the total surplus value, as we saw, will be $= (5 \times 12)/4\ M$ (month) $= 5 \times 3 = 15$; instead of 20 as when $c = 0$; for then $S' = (5 \times 12)/3 = 20$. But now 15 is the gain on a capital of 75 at 5% whose circulation time = 0; which turned over 4 times a year; was continuously occupied. At the end of the first quarter 3 3/4; at the end of the year 15. (But only a total capital of 300 would turn over; while one of 400 if in the above case $ct = 0$.) Hence a capital of 100, with respect to which circulation time amounts to 1 month on every 3 M production time, can constantly employ productively a capital of 75; a capital of 25 is constantly circulating and unproductive. $75{:}25 = 3\ M{:}1\ M$, or, if we call the part of the capital occupied in production p, the part in circulation c, and the corresponding times c' and p', then $p{:}c = p'{:}c'$ ($p{:}c = 1{:}1/3$). The part of the C in production constantly relates to the part in circulation as 1:1/3; this 1/3 constantly represented by changing component parts. But $p{:}C = 75{:}100 = 3/4$; $c = 1/4$; $p{:}C = 1{:}4/3$ and $c{:}C = 1{:}4$. The total turnover $= 4\ M$, $p{:}R = 3\ M{:}4\ M = 1{:}4/3$.

Change of form and of matter in the circulation of capital. – C–M–C. M–C–M.

A change of form [*Formwechsel*] and a change of matter [*Stoffwechsel*] take place simultaneously in the circulation of capital. We must begin here not with the presupposition of M, but with the production process. In production, as regards the material side, the instrument is used up and the raw material is worked up. The result is the product – a newly created use value, different from its elemental presuppositions. As regards the material side, a product is created only in the production process. This is the first and essential material change. On the market, in the exchange for money, the product is expelled from the circulation of capital and falls prey to consumption, becomes object of consumption, whether for the final satisfaction of an individual need or as raw material for another capital. In the exchange of the commodity for money, the material and the formal changes coincide; for, in money, precisely the content itself is part of the economic form. The retransformation of money into commodity is here, however, at the same time present in the retransformation of capital into the material conditions of production. The reproduction of a specific use value takes place, just as well as of value as such. But, just as the material element here was posited, from the outset, at its entry into circulation, as a product, so the commodity in turn was posited as a condition of production at the end of it. To the extent that money figures here as medium of circulation, it does so indeed only as mediation of production, on one side with consumption, in the exchange where capital discharges value in the form of the product, and as mediation, on the other side, between production and production, where capital discharges itself in the form of money and draws the commodity in the form of the condition of production into its circulation. Regarded from the material side of capital, money appears merely as a medium of circulation; from the formal side, as the nominal measure of its realization, and, for a specific phase, as value-for-itself; capital is therefore C–M–M–C just as much as it is M–C–C–M, and this in such a way, specifically, that both forms of simple circulation here continue to be determinants, since M–M is money, which creates money, and C–C a commodity whose use value is both reproduced and increased. In regard to money circulation, which appears here as being absorbed into and determined by the circulation of capital, we want only to remark in passing – for the matter can be thoroughly treated only after the many capitals have been examined in their action and reaction upon one another – that money is obviously posited in different aspects here.

Difference between production time and labour time. **– Storch.** ***Money. Mercantile estate. Credit. Circulation***

Until now it has been assumed that production time coincides with labour time. But now there take place, e.g. in agriculture, interruptions of work within the production process itself, before the product is finished. The same labour time may be applied and the duration of the production phase may differ, because work is interrupted. If the difference is only that the product in one case requires a longer working time in order to be finished than in another case, then no case at all is constituted, because it is then clear according to the general law that the product in which a greater quantity of labour is contained is of that much greater value, and if the reproduction is less frequent in a given period of time, then the reproduced value is all the greater. And 2 × 100 is just as much as 4 × 50. As with the total value, then, so with the surplus value. The question is constituted by the unequal duration required by different products, although the same amount of labour time (namely stored-up and living labour together) is employed upon them. The fixed capital here allegedly acts quite by itself, without human labour, like e.g. the seed entrusted to the earth's womb. In so far as additional labour is required, this is to be deducted. The question to be posed in pure form. If circulation time here the same, then the turnover is less frequent because the production phase longer. Hence production time + turnover time = 1*R*, larger than in the case where production time coincides with labour time. The time required here for the product to reach maturity, the interruptions of work, here constitute conditions of production. Not-labour time constitutes a condition for labour time, in order to turn the latter really into production time. The question obviously belongs only with the equalization of the rate of profit. Still, the ground must be cleared here. The slower return – this is the essential part – here arises not from circulation time, but rather from the conditions themselves in which labour becomes productive; it belongs with the technological conditions of the production process. It must absolutely be denied, it is downright nonsensical to claim, that a natural circumstance which hinders a capital in a specific branch of production from exchanging with the same amount of labour time in the same amount of time as another capital in another branch of production can in any way contribute to *increasing* the former's value. Value, hence also surplus value, is not = to the time which the production phase lasts, but rather to the labour time, objectified and living, employed during this production phase. The living labour time alone – and, indeed, in the proportion in which it is employed relative to objectified labour time – can create surplus value, because [it creates] surplus labour time. * It has therefore correctly been asserted that in this regard agriculture for instance is less productive (productivity is concerned here with the production of values) than other industries. Just as in another respect – *in so far as a growth of productivity in it* DIRECTLY *reduces necessary labour time – it is more productive than all the others.* But this circumstance can accrue to its advantage only where *capital* already rules, together with the general form of production corresponding to it. This interruption in the production phase already signifies that agriculture can never be the sphere in which capital starts; the sphere in which it takes up its original residence. This contradicts the primary fundamental conditions of industrial labour. Hence agriculture is claimed for capital and becomes industrial only retroactively. Requires a high development of competition on one side, on the other a great development of chemistry, mechanics etc., i.e. of manufacturing industry. History shows, consequently, that agriculture never *appears in pure form* in the modes of production preceding capital, or which correspond to its own undeveloped stages. A rural secondary industry, such as spinning, weaving etc. must make up for the limit on the employment of labour time posited here – and located in these interruptions. The non-identity of production time with labour time can be due generally only to natural conditions, which stand directly in the path of the realization of labour, i.e. the appropriation of surplus labour by capital. These obstacles in its path do not of course constitute advantages, but rather, from its point of view, losses. The whole case is worth mentioning here actually only as an example of fixated capital, capital fixated in one phase. The point to remember here is only that capital creates no surplus value as long as it employs no living labour. The reproduction of the employed fixed capital itself is of course not the positing of surplus value.

* It is clear that other aspects also enter in with the equalization of the rate of profit. Here, however, the issue is not the distribution of surplus value but its creation.

(In the human body, as with capital, the different elements are not exchanged at the same rate of reproduction, blood renews itself more rapidly than muscle, muscle than bone, which in this respect may be regarded as the fixed capital of the human body.)

As means of speeding up circulation, Storch lists: (1) formation of a class of ‘workers’ who busy themselves only with trade; (2) easy means of transport; (3) money; (4) credit. (See above.) [61]

This motley combination reveals the whole confusion of the political economists. Money and money circulation – what we called simple circulation – is the presupposition, condition, of capital itself, as well as of the circulation of capital. Money as it exists, hence, as a relation of intercourse belonging to a stage of production preceding capital, money as money, in its immediate form, can therefore not be said to speed up the circulation of capital, but is rather its presupposition. When we speak of capital and of its circulation, we stand on a stage of social development where the introduction of money does not enter as a discovery etc., but is rather a *presupposition.* To the extent that money in its immediate form itself has value, and is not merely the value of other commodities, the symbol of their value – for, if something which is itself immediate is supposed to be something else which is also immediate, then it can only *represent* the latter, in one way or another, as symbol – but rather, itself has value, is itself objectified labour in a specific use value, to that extent, money, so far from speeding up the circulation of capital, rather delays it. Regarded in both of the aspects in which it occurs in the circulation of capital, both as medium of circulation and as the realized value of capital, money belongs among the costs of circulation in so far as it is itself labour time employed to abbreviate circulation time on the one hand, and, on the other hand, to represent a qualitative moment of circulation – the retransformation of capital into itself as value-for-itself. In neither aspect does it increase the value. In one aspect it is a precious form of representing value, i.e. a costly form, costing labour time, hence representing a deduction from surplus value. In the other aspect it can be regarded as a machine which saves circulation time, and hence frees time for production. But, in so far as it itself, as such a machine, costs labour and is a product of labour, it represents for capital *faux frais de production.* It figures among the costs of circulation. The original cost of circulation is circulation time itself as opposed to labour time. The real costs of circulation are themselves objectified labour time – machinery for the purpose of abbreviating the original costs of circulation. Money in its immediate form, as it belongs to a historic stage of production preceding capital, thus appears to capital as a cost of circulation, and the efforts of capital hence tend in the direction of transforming it into a form adequate for its own ends; hence attempting to make it into a representative of one moment of circulation which does not itself cost labour, and has itself no value. Capital hence tends in the direction of suspending money in its inherited, immediate reality, and transforming it into something merely *posited* and at the same time suspended by capital, into something purely *ideal.* It cannot be said, therefore, as does Storch, that money as such is a means of speeding up the circulation of capital; it must rather be said to the contrary that capital attempts to transform money into a merely *ideal* moment of its circulation, and first to raise it into the adequate form corresponding to it. Suspension of money in its immediate form appears as a demand made by money circulation once it has become a moment of the circulation of capital; because in its immediate, presupposed form it is a *barrier* to the circulation of capital. The tendency of capital is *circulation without circulation time;* hence also the positing of the instruments which merely serve to abbreviate circulation time as mere *formal aspects* posited by it, just as the different moments through which capital passes in its circulation are qualitative aspects of its own metamorphosis.

As regards the formation of a special mercantile estate – i.e. a development of the division of labour which has transformed the business of exchanging into a particular kind of work – for which, of course, the sum of exchange operations must already have reached a certain height – (if the exchange among 100 people occupied the 100th part of their labour time, then each man is 1/100 of an exchanger; 100/100 exchangers would represent one single man. Then one merchant could arise per 100. The separation of commerce from production itself, or the development of exchange itself as a representation opposite the exchangers, requires as such that exchange and intercourse have developed to a certain degree. The merchant represents all buyers to the seller, all sellers to the buyer and vice versa, hence he is not an extreme, but rather the middle of the exchange itself; appears hence as mediator, middleman) – the formation of the merchant estate, which presupposes that of money, even if not developed in all its moments, is likewise a presupposition for capital, and hence cannot be listed as being a mediator of its specific circulation. Since commerce is both historically as well as conceptually a presupposition for the rise of capital, we shall have to return to it before concluding this chapter, since it belongs before or in the section on the origin of capital.

The facilitation of the means of transport, to the extent that it means facilitation of the physical circulation of commodities, does not belong here, where we are examining merely the characteristic forms of the circulation of capital. The product becomes a commodity, leaves the production phase, only when it is on the *market.* On the other side, the means of transportation do belong here in so far as the *returns* of capital – i.e. circulation time – must grow with the distance of the market from the point of production. Its abbreviation by means of transport thus appears as belonging directly, in this respect directly, to the examination of the circulation of capital. But this actually belongs to the doctrine of the market, which itself belongs to the section on capital.

Finally, *credit.* This form of circulation etc. directly posited by capital – which arises, hence, specifically from the nature of capital, this specific characteristic of capital – is mixed up here by Storch etc. together with money, mercantile estate, etc., which belong generally with the development of exchange and of the production more or less founded on it. The presentation of the specific, distinguishing characteristics is here both the *logical* development and the key to the understanding of the *historical* development. Thus we find in history, too, e.g. in England (likewise in France), [attempts] to replace money by paper; then also to give capital, in so far as it exists in the form of *value,* a form purely posited by itself; finally attempts to found credit directly with the rise of capital. (E.g. Petty, Boisguillebert.)

Small-scale circulation. The process of exchange between capital and labour capacity generally. Capital in the reproduction of labour capacities

Within circulation as the total process, we can distinguish between large-scale and small-scale circulation. The former spans the entire period from the moment when capital exits from the production process until it enters it again. The second is continuous and constantly proceeds simultaneously with the production process. It is the part of capital which is paid out as wages, exchanged for labouring capacity. The circulation process of capital, which is posited in the form of an exchange of equivalents, but is in fact suspended as such, and posited as such only formally (the transition from value to capital, where the exchange of equivalents turns into its opposite, and where, on the basis of exchange, exchange becomes purely formal, and the mutuality is all on one side), is to be developed in this way: Values which become exchanged are always objectified labour time, an objectively available, *reciprocally* presupposed quantity of labour (present in a use value). Value as such is always an effect, never a cause. It expresses the amount of labour by which an object is produced, hence – presupposing the same stage of the productive forces – the amount of labour by which it can be reproduced. The capitalist does not exchange capital directly for labour or labour time; but rather time contained, worked up in commodities, for time contained, worked up in living labour capacity. The living labour time he gets in exchange is not the exchange value, but the use value of labour capacity. Just as a machine is not exchanged, paid for as cause of effects, but as itself an effect; not according to its use value in the production process, but rather as product – definite amount of objectified labour. The labour time contained in labour capacity, i.e. the time required to produce living labour capacity, is the same as is required – presupposing the same stage of the productive forces – to reproduce it, i.e. to maintain it. Hence, the exchange which proceeds between capitalist and worker thus corresponds completely to the laws of exchange; it not only corresponds to them, but also is their highest development. For, as long as labour capacity does not itself exchange itself, the foundation of production does not yet rest on exchange, but exchange is rather merely a narrow circle resting on a foundation of non-exchange, as in all stages preceding bourgeois production. But the use value of the value the capitalist has acquired through exchange is itself the element of realization and its measure, living labour and labour time, and, specifically, more labour time than is objectified in labour capacity, i.e. more labour time than the reproduction of the living worker costs. Hence, by virtue of having acquired labour capacity in exchange as an equivalent, capital has acquired labour time – to the extent that it exceeds the labour time contained in labour capacity – in exchange *without equivalent;* it has appropriated alien labour time *without exchange* by means of the *form* of exchange. This is why exchange becomes merely formal, and, as we saw, in the further development of capital even the semblance is suspended that capital exchanges for labour capacity anything other than the latter's own objectified labour; i.e. that it exchanges anything at all for it. The turn into its opposite [*Umschlag*] therefore comes about because the ultimate stage of free exchange is the exchange of labour capacity as a commodity, as value, for a commodity, for value; because it is given in exchange as objectified labour, while its use value, by contrast, consists of living labour, i.e. of the positing of exchange value. The turn into its opposite arises from the fact that the use value of labour capacity, as value, is itself the value-creating force; the substance of value, and the value-increasing substance. In this exchange, then, the worker receives the equivalent of the labour time objectified in him, and gives his value-creating, value-increasing living labour time. He sells himself as an effect. He is absorbed into the body of capital as a cause, as activity. Thus the exchange turns into its opposite, and the laws of private property – liberty, equality, property – property in one's own labour, and free disposition over it – turn into the worker's propertylessness, and the dispossession [*Entäusserung*] of his labour, [i.e.] the fact that he relates to it as alien property and vice versa.

The circulation of the part of capital which is posited as wages accompanies the production process, appears as an economic form-relation alongside it, and is simultaneous and interwoven with it. This circulation alone posits capital as such; is the condition of its realization process, and posits not only the latter's characteristic form, but also its substance. This is the constantly circulating part of capital, which at no time enters into the production process itself, [but] constantly accompanies it. It is the part of capital which does not even for a single instant enter into its reproduction process, which is not the case with raw material. The worker's *approvisionnement* arises out of the production process, as product, as result; but it never enters as such into the production process, because it is a finished product for individual consumption, enters directly into the worker's consumption, and is directly exchanged for it. This, therefore, as distinct from raw material as well as instrument, is the circulating capital κατ᾽ ἐξοχήν. Here is the only moment in the circulation of capital where consumption enters directly. At the point where the commodity becomes exchanged for money, it may be acquired by another capital as raw material for new production. Further, given the presuppositions, capital encounters not the individual consumer but rather the merchant; someone who buys the commodity itself in order to sell it for money. (This presupposition is to be developed in connection with the merchant estate in general. The circulation among dealers thereby different from that between dealers and consumers.) Thus the circulating capital here appears directly as that which is specified for the workers' individual consumption; specified for direct consumption generally, and hence existing in the form of finished product. Thus, while in one respect capital appears as the presupposition of the product, the finished product also at the same time appears as the presupposition of capital – which means, historically, that capital did not begin the world from the beginning, but rather encountered production and products already present, before it subjugated them beneath its process. Once in motion, proceeding from itself as basis, it constantly posits itself ahead of itself in its various forms as consumable product, raw material and instrument of labour, in order constantly to reproduce itself in these forms. They appear initially as the conditions presupposed by it, and then as its result. In its reproduction it produces its own conditions. Here, then – through the relation of capital to living labour capacity and to the natural conditions of the latter's maintenance – we find circulating capital specified in respect of its use value as well, as that which enters directly into individual consumption, to be directly used up by the latter. It is a mistake to conclude from this, as has been done, [62] that circulating capital is therefore *consumable* capital generally, as if coal, oil, dye etc., instruments etc., improvements of the land etc. factories etc. were not all consumed likewise, if by consumption is meant the suspension of their use value and of their form; however, one could just as well say that none of them is consumed, if this is taken to mean individual consumption, i.e. consumption in the proper sense. In this circulation, capital constantly expels itself as objectified labour, in order to assimilate living labour power, its life's breath. Now, as regards the worker's consumption, this reproduces one thing – namely himself, as living labour capacity. *Because this, his reproduction, is itself a condition for capital, therefore the worker's consumption also appears as the reproduction not of capital directly, but of the relations under which alone it is capital. Living labour capacity belongs just as much among capital's conditions of existence as do raw material and instrument. Thus it reproduces itself doubly, in its own form, [and] in the worker's consumption, but only to the extent that it reproduces him as living labour capacity.* Capital therefore calls this consumption productive consumption – productive not in so far as it reproduces the individual, but rather individuals as labour capacities. If Rossi is offended that wages are allegedly counted twice, first as the worker's revenue, then as reproductive consumption of capital, [63] then the objection holds only against those who let wages enter directly into the production process of capital as value. For the payment of wages is an act of circulation which proceeds simultaneously with and alongside the act of production. Or, as Sismondi says from this perspective – the worker consumes his wages unreproductively; but the capitalist consumes them productively, since he gets labour in the exchange, which reproduces the wages and more than the wages. This concerns capital itself regarded merely as an object. But in so far as capital is a relation, and, specifically, a relation to living labour capacity, [to that extent] the worker's consumption reproduces this relation; or, capital reproduces itself doubly, as value through purchase of labour – as a possibility of beginning the realization process anew, of acting as capital anew – and as a relation through the worker's consumption, which reproduces him as labour capacity exchangeable for capital – wages as part of capital.

This circulation between capital and labour, then, yields the characterization of one part of capital as constantly circulating, the *approvisionnement;* constantly consumed; constantly to reproduce. This circulation strikingly reveals the difference between capital and money; the circulation of capital and the circulation of money. Capital pays wages e.g. weekly; the worker takes his wages to the grocer etc.; the latter directly or indirectly deposits them with the banker; and the following week the manufacturer takes them from the banker again, in order to distribute them among the same workers again, etc. and so forth. The same sum of money constantly circulates new portions of capital. The sum of money itself, however, does not determine the portions of capital which are thus circulated. If the money value of wages rises, then the circulating medium will increase, but the mass of the medium does not determine the rise. If the production costs of money did not fall, then no increase of money would exercise an influence on the portion of it entering into this circulation. Here money appears as mere medium of circulation. Since many workers are to be paid at the same time, a certain sum of money is required at one time, which grows with the number of workers. Then, however, the velocity of the circulation of the money makes a lesser sum necessary than in situations where there are fewer workers but the machinery of monetary circulation is not so arranged. This circulation is a condition of the production process and thereby of the circulation process as well. On the other hand, if capital does not return from circulation, then this circulation between worker and capital could not begin anew; hence it is itself conditional upon capital passing through the various moments of its metamorphosis *outside* the production process. If this did not happen, it would be not because there was not enough *money* as *medium of circulation,* but rather either because capital was not available in the form of products, because this part of *circulating* capital was lacking, or because capital did not posit itself in the *form of money,* i.e. did not realize itself as capital, which in turn, however, would arise not from the quantity of the medium of circulation, but because capital did not posit itself in the *qualitative aspect* of money, which in no way requires that it posit itself in the form of hard cash, in the immediate money form; and whether or not it posited itself in that form would again depend not on the quantity of money circulating as medium of circulation, but rather on the exchange of capital for value as such; again a qualitative, not a quantitative, moment, as we shall point out in more detail when we speak of capital as money. (Interest etc.)

Threefold character, or mode, of circulation. – *Fixed capital and circulating capital. – Turnover time of the total capital divided into circulating and fixed capital. – Average turnover time of such a capital. – Influence of fixed capital on the total turnover time of capital. – Circulating fixed capital.* Say. Smith. Lauderdale. *(Lauderdale on the origin of* profit)

Regarded as a whole, circulation thus appears threefold: (1) the total process – the course of capital through its different moments; accordingly, it is posited as being in flow; as circulating; in so far as the continuity is virtually interrupted, and may resist the passage into the next phase, capital here likewise appears as fixated in different relations, and the various modes of this fixation constitute different capitals, commodity capital, money capital, capital as conditions of production.

(2) Small-scale circulation between capital and labour capacity. This accompanies the production process and appears as contract, exchange, form of

intercourse; these things are presupposed before the production process can be set going. The part of capital entering into this circulation – the approvisionnement – is circulating capital κατ᾽ ἐξοχήν. It is specified not only in respect to its form; in addition to this, its use value, i.e. its material character as a consumable product entering directly into individual consumption, itself constitutes a part of its form.

(3) Large-scale circulation; the movement of capital outside the production phase, where its time appears in antithesis to labour time, as circulation time. The distinction between *fluid* and *fixed capital* is the product of this opposition between the capital engaged in the production phase and the capital which issues from it. Fixed is that which is fixated in the production process and is consumed within it; comes out of large-scale circulation, certainly, but does not return into it, and, in so far as it circulates, circulates only in order to be consumed in, confined to, the consumption process.

The three different distinctions in the circulation of capital yield the three distinctions between circulating and fixated capital; they posit one part of capital as circulating κατ᾽ ἐξοχήν, because it never enters into the production process, but constantly accompanies it; and thirdly, [they yield] the distinction between *fluid* and *fixed* capital. Circulating capital in form No. 3 also includes No. 2, since the latter is also in antithesis to the fixed; but No. 2 does not include No. 3. The part of capital which belongs as such to the production process is the part of it which serves, materially, only as *means of production;* forms the link between living labour and the material to be worked on. A part of the liquid capital, such as coal, oil etc., also serves merely as means of production. Everything which serves merely as a means to keep the machine, or the engine, running. This distinction will have to be examined yet more closely. First of all, this does not contradict aspect 1, since the fixed capital as *value* also circulates in proportion as it is worn out. Precisely in this aspect as *fixed* capital – i.e. in the character in which capital has lost its fluidity and become identified with a *specific* use value, which robs it of its ability to transform itself – does *developed capital* – to the extent we know it so far, as productive capital – most strikingly manifest itself, and it is precisely in this seemingly inadequate form, and in the latter’s increasing relation to the form of circulating capital in No. 2, that the development of capital as capital is measured. This contradiction pretty. To be developed.

The different kinds of capital, which, in economics, fall out of the sky, here appear as so many precipitates of the movements arising out of the nature of capital itself, or rather of this movement itself in its different moments.

Circulating capital constantly ‘parts’ from the capitalist, in order to return to him in the first form. *Fixed capital* does not (Storch). [64] *‘Circulating capital* is that portion of the capital which does not yield profit *till it is parted with;* fixed etc. yields such profit, *while it remains in the possession of the owner.’* (Malthus.) [65] ‘Circulating capital gives its master no revenue or profit, *so long as it remains in his possession; fixed capital* gives this profit without changing masters, and without requiring circulation.’ (A. Smith.) [66]

In this respect, since capital’s departure on a voyage away from its owner (*‘partir de son possesseur’*) [67] means nothing more than the *sale* of property or possessions which takes place in the act of exchange, and since it is the nature of all exchange value, hence all capital, to become value for its owner by means of sale, the definition in its above formulation cannot be correct. If fixed capital were [capital] for its owner without the mediation of exchange and of the use value [68] included in it, then, in fact, fixed capital would be a mere use value, hence not capital. But the basis of the above definition is this: fixed capital circulates as *value* (even if only in portions, successively, as we shall see). It does not circulate as *use value.* As far as its material aspect is concerned, as a moment of the production process, *fixed capital* never leaves its boundaries; is not sold by its possessor; remains in his hand. It circulates as capital only in its *formal aspect,* as self-eternalizing value. This distinction between form and content, use value and exchange value, does not take place in circulating capital. In order to circulate, to exist, as the latter, it has to step into circulation as the former, must be sold. Use value for *capital* as such is only value itself. Circulating capital realizes itself as value for capital as such only when it is sold. As long as it remains in its hand, it only has value *in itself;* but it is not *posited;* only in potency – but not in act. Fixed capital, by contrast, realizes itself as value only as long as it remains in the capitalist’s hand as a use value, or, expressed as an objective relation, as long as it remains in the production process, which may be regarded as the inner organic movement of capital, its relation to itself, as opposed to its animal movement, its presence for another. Hence, since *fixed capital,* once it has entered the production process, remains in it, it also passes away in it, is consumed in it. The duration of this consumption does not yet concern us here. In this respect, then, *fixed capital* also includes what Cherbuliez calls the *matières instrumentales,* [69] such as coal, oil, wood, grease etc., which are completely destroyed in the production process, which only have a *use value* for the process of production itself. The same materials, however, also have a use value outside production, and can also be consumed in another way, just as buildings, houses, etc. are not necessarily specified for production. They are *fixed capital* not because of the specific mode of their being, but rather because of their use. They become fixed capital as soon as they step into the production process. They are *fixed capital,* as soon as they are posited as moments of the production process of capital; because they then lose their property of being potentially circulating capital.

Therefore, just as the part of capital entering into the small-scale circulation of capital – or capital, in so far as it enters into this movement – circulation between capital and labour capacity, the part of capital circulating as wages – *never leaves the circulation process and never enters into the production process of capital,* as regards its material aspect, as use value, but rather is always ejected from a previous production process as its product, result, so, inversely, does the part of capital specified as *fixed capital,* as a use value, as regards its material presence, never leave the *production process* and *never go back into circulation.* While the latter only enters into circulation as *value* (as part of the value of the finished product), the former only enters into the production process as *value,* in that necessary labour is the reproduction of wages, of the part of the capital's value which circulates as wages. This, then, is the *first* characteristic of fixed capital, and in this respect it also includes the *matières instrumentales.*

Secondly: Fixed capital can enter into circulation as value, however, only to the extent that it passes away as use value in the production process. It passes, as value, into the product – i.e. as labour time worked up or stored up in it – in so far as it passes away in its independent form as use value. In being used, it is used up, but in such a way that its value is carried over from its form into the form of the product. If it is not used, not consumed in the production process itself – if the machinery stands still, the iron rusts, the wood rots – then of course its value passes away together with its transitory presence as use value. Its circulation as value corresponds to its consumption in the production process as use value. Its total value is completely reproduced, i.e. is fully returned via circulation only when it has been completely consumed as use value in the production process. As soon as it is completely dissolved into value, and hence completely absorbed into circulation, it has completely passed away as use value and hence must be replaced, as a necessary moment of production, by a new use value of the same kind, i.e. must be reproduced. The necessity of reproducing it, i.e. its reproduction time, is determined by the time in which it is used up, consumed within the production process. With circulating capital, reproduction is determined by circulation time; with fixed capital, circulation is determined by the time in which it is consumed as use value, in its material presence, within the act of production, i.e. by the period of time within which it must be reproduced. A thousand pounds of twist can be reproduced as soon as they are sold and the money obtained for them is again exchanged for cotton, in short, for the elements of the production of twist. Their reproduction is determined, hence, by circulation time. A machine of a value of £1,000 which lasts 5 years, which is used up in 5 years and then becomes nothing more than scrap iron, is used up, say, by 1/5 per year, if we take the average consumption in the production process. Hence every year only 1/5 of its value enters into circulation, and only with the passing of the 5 years has it completely gone into circulation and returned from it. Its entry into circulation is thus purely determined by the time of its wearing out; and the time which its value needs to enter totally into circulation and to return from it is determined by its total reproduction time, the time in which it must be reproduced. Fixed capital enters into the product only as value; while the use value of circulating capital has remained in the product as the latter’s substance, and has merely obtained another form. This distinction essentially modifies the *turnover time* of a total capital divided into circulating and fixed capital. Let total capital = S; its circulating part = c; its fixed part = f; let the fixed capital form $1/x\ S$; the circulating capital S/y. Let the circulating capital turn over 3 times a year, the fixed capital only twice every 10 years. In 10 years, f or S/x will turn over twice; while in the same 10 years S/y will turn over $3 \times 10 = 30$ times. If S were =

S/y, i.e. circulating capital only, then R, its turnover, would be = 30; and the total capital turned over = 30 × S/y; the total capital turned over in 10 years. But the fixed capital turns over only twice in 10 years. Its $R' = 2$; and the total fixed capital turned over = $2S/x$. But $S = S/y + S/x$ and its total turnover time = the total turnover time of both these parts. If the fixed capital turns over twice in 10 years, then in one year 2/10 or 1/5 of it turns over; while in one year the circulating capital turns over 3 times. $S/5x$ turns over once a year.

The question simply this: if a capital of 1,000 thalers = 600 circulating capital and 400 fixed capital; thus 3/5 circulating and 2/5 fixed capital; if the fixed capital lasts 5 years, hence turns over once in 5 years and the circulating turns over 3 times a year, then what is the average turnover or turnover time of the total capital? If it were circulating capital only, then it would turn over 5 × 3, 15 times; the total capital turned over in the 5 years would be 15,000. But 2/5 of it turn over only once in 5 years. Hence, of the 400 thalers, 400/5 = 80 thalers turn over in one year. Of the 1,000 thalers, 600 annually turn over 3 times, 80 once; or, in one year, only 1,880 would turn over; hence in 5 years 5 ×1,880 = 9,400 turn over; i.e. 5,600 less than if the total capital consisted only of circulating capital. If the entire capital consisted only of circulating capital, then it would turn over once in 1/3 of a year.

If the capital = 1,000; $c = 600$, turns over twice a year; $f = 400$, turns over once a year; then 600 (3/5 S) turns over in half a year; 400/2 or $2S/(5 \times 2)$ likewise in half a year. Hence in half a year, 600 + 200 = 800 (i.e. $c + f/2$) turns over. IN A WHOLE YEAR, hence, 2 × 800 or 1,600 turn over; 1,600 thalers in 1 year; hence 100 in 12/16 months, hence 1,000 in 120/16 months = 7 1/2 months. The total capital of 1,000 thus turns over in 7 1/2 months, while it would turn over in 6 months if it consisted of circulating capital only. 7 1/2: 6 = 1:1 1/4 or as 1:5/4. If the capital = 100, circulating = 50, fixed = 50; the former turns over twice a year, the latter once; then 1/2 100 turns over once in 6 months; and 1/4 100 likewise once in 6 months; hence in 6 months 3/4 of the capital turns over, 3/4 100 in 6 months; or 75 in 6 months, and 100 in 8 months. If 2/4 100 turn over in 6 months, and in the same 6 months 1/4 100 (1/2 of the fixed capital), then 3/4 100 turn over in 6 months. Hence 1/4 in 6/3 = 2 [months]; hence 4/4 100 or 100 in 6 + 2, in 8 months. The total turnover time of the capital = 6 (the turnover time of the entire circulating capital and 1/2; of the fixed capital or 1/4 of the total capital) + 6/3 i.e. + this turnover time divided by the number expressing the ratio of the remaining fixed capital to the capital turned over in the turnover time of circulating capital. Thus in the above example: 3/5 100 turns over in 6 months; ditto 1/5 100; hence 4/5 100 in 6 months; hence the remaining 1/5 100 in 6/4 months; hence the total capital in 6 + 6/4 months = 6 + 1 1/2 or 7 1/2 months. Thus, expressed in general terms:

Average turnover time = the turnover time of circulating capital + this turnover time divided by the number which expresses how often the remaining part of the fixed capital is contained in the total sum of the capital which was circulated in this turnover time.

If there are two capitals of 100 thalers, one of them entirely composed of circulating capital, the other half fixed capital, each at 5% profit, the one turning over twice a year, and in the other the circulating capital likewise twice, but the fixed capital only once; then the total capital turning over would be = 200 in the first case, and the profit = 10; in the second = 3 turnovers in 8 months, 1 1/2 in 4; or 150 would turn over in 12 months; profit then = 7 1/2. This kind of calculation has strengthened the common prejudice that circulating capital or fixed capital through some mysterious innate power brings a gain, as even in Malthus's phrase 'the circulating capital brings a gain when its possessors part with it etc.'; [70] likewise, in the above-quoted lines from his *Measure of Value* etc., the way in which he makes fixed capital accumulate profits. [71] The greatest confusion and mystification has arisen because the doctrine of surplus profit has not been examined in its pure form by previous economists, but rather mixed in together with the doctrine of real profit, which leads up to distribution, where the various capitals participate in the general rate of profit. The profit of the capitalists as a class, or the profit of *capital* as such, has to exist before it can be distributed, and it is extremely absurd to try to explain its origin by its distribution. According to the above, profit declines because the turnover time of capital increases * in proportion as the component part of it which is called fixed capital increases. A capital of the same size, 100 in the above case, would turn over entirely twice a year if it consisted only of a circulating capital. But it turns over only twice in 16 months, or only 150 thalers are turned over in one year, because half of it consists of fixed capital. As the number of its reproductions in a given period declines, or the amount of it reproduced in this given time declines, so does the production of surplus time or surplus value decline, since capital posits value at all only in so far as it posits surplus value. (This at least is its tendency, its adequate action.)

> * Its size posited as permanent – this does not concern us here at all, since the statement is true for a capital of any size. Capitals have different sizes. But the size of each individual capital is *equal to itself,* hence, in so far as only its quality as capital is concerned, any size. But if we examine two capitals in comparison to each other, then the difference in their size introduces a relation of a qualitative characters. Size becomes itself a distinguishing quality. *This is an essential aspect,* of which size is only one single instance, of how the study of capital as such differs from the study of one capital in relation to another capital, or the study of capital in its reality.

Fixed capital, as we saw, circulates as value only to the degree that it is used up or consumed as use value in the production process. But the time in which it is consumed and in which it must be reproduced in its form as use value depends on its relative durability. Hence its durability, or its greater or lesser perishability – the greater or smaller amount of time during which it can continue to perform its function within the repeated production processes of capital – this aspect of its use value here becomes a form-determining moment, i.e. a determinant for capital as regards its form, not as regards its matter. The necessary reproduction time of fixed capital, together with the proportion of the total capital consisting of it, here modify, therefore, the turnover time of the total capital, and thereby its realization. The greater durability of capital (the diminution (duration) of its necessary reproduction time) and the proportion of fixed capital to the total capital, then, here influence realization just as does a slower turnover due either to a greater distance in space of the market from which the capital returns as money, so that a longer time is required to complete the path of circulation (as e.g. capitals working in England for the East India market return more slowly than those working for nearer foreign markets or for the domestic market), or to the production phase being itself interrupted by natural conditions, as in agriculture. Ricardo, who was the first to emphasize the influence of fixed capital on the realization process, throws all these aspects into one motley heap, as one can see from the excerpts quoted above. [72]

In the first case (fixed capital), the turnover of capital is reduced because the fixed capital is consumed slowly within the production process; or the cause lies in the duration of the time required for its reproduction. In the second case the reduced turnover arises from the prolongation of *circulation time* (in the first case the fixed capital necessarily always circulates as rapidly as the product, *in so far as* it circulates, enters circulation at all, because it circulates not in its material existence, but only as value, i.e. as an ideal component part of the total value of the product) and, specifically, from the circulation time of the second half of the circulation process proper, the retransformation into money; in the third case the reduced turnover arises from the longer time the capital requires, not, as in the first case, to pass away in the production process, but rather to emerge from it as product. The first case is peculiar specifically to fixed capital; the other belongs to the category of capital which is not liquid, but fixated, fixated in one or another phase of the total circulation process (fixed capital of a considerable degree of durability, *or* circulating capital returnable at distant periods. McCulloch, *Principles of Political Economy.* Notebook, p. 15.) [73]

Thirdly: We have regarded fixed capital so far only from the aspect in which its particular relation, its specific relation, distinguishes it from the circulation process proper. Still further distinctions will arise in this respect. Firstly, the return of its value in successive parts, whereas each part of circulating capital is exchanged in its entirety; this because in the former, the existence of the value coincides with that of the use value. Secondly, not merely [because of] its influence on the average turnover time of a given capital, as we have indicated up to now, but also [because of] its own turnover time. The latter circumstance becomes important where the fixed capital appears not as a mere instrument of production within the production process, but rather as an independent form of capital, e.g. in the form of railways, canals, roads, aqueducts, improvements of the land, etc. This latter aspect becomes notably important for the proportion in which the total capital of a country is divided into these two forms. Then, the way in which it is renewed and maintained; which the economists formulate in the form that it can bring revenue only by means of circulating capital etc. This last is basically nothing but the examination of the moment where it appears, not as a particular independent existence *alongside* and *outside* circulating capital, but rather as circulating capital transformed into fixed capital. But what we want to examine here first of all is the relation of fixed capital not towards the outside, but rather the extent to which the relation is given through its continued enclosure within the production process. It is thereby posited that it is a definite moment of the production process itself.

<It is not necessarily the case that *fixed capital* is capital which in all its aspects serves not for individual consumption, but only for production. A house can serve for production as well as for consumption; likewise all vehicles, a ship and a wagon, for pleasure outings as well as a means of transport; a street as a means of communication for production proper, as well as for taking walks etc. *Fixed capital* in this second aspect does not concern us here at all, since we regard capital here only as process of realization and process of production. The second aspect will enter when we study interest. Ricardo can have only this aspect in mind when he says: 'Depending on whether the capital is more or less perishable, hence must be more or less frequently reproduced in a given time, it is called circulating or fixed capital.' (Ricardo, VIII, 19.) [74] According to this, a coffee-pot would be fixed capital, but coffee circulating capital. The crude materialism of the economists who regard as the *natural properties* of things what are social relations of production among people, and qualities which things obtain because they are subsumed under these relations, is at the same time just as crude an idealism, even fetishism, since it imputes social relations to things as inherent characteristics, and thus mystifies them. (The difficulty of defining a thing as fixed capital or circulating capital on the basis of its natural qualities has here, by way of exception, led the economists to the discovery that things in themselves are neither fixed nor circulating, hence not capital at all, any more than it is a natural quality of gold to be money.)>

(Also included in the points listed above, so that it is not forgotten, is the circulation of fixed capital as circulating capital, i.e. transactions through which it changes its owners.)

'Fixed capital – *tied up:* capital so *tied up in one kind of production* that it can no longer be diverted to *another kind of production.*' (Say, 24.) [75] 'Fixed capital is consumed in order to help produce the things useful to man … it consists of *durable foundations which increase the productive powers of future labour.*' (Sismondi, VI) [76] *'Fixed capital* the capital necessary to maintain the instruments, machines etc. of labour.' (Smith, Vol. II, p. 226.)

‘Floating capital is consumed, fixed capital merely used in the great work of production.’ (*Economist,* Notebook VI, p. 1.) [77] ‘We shall show that the first stick or the first stone which he took in his hand to assist him in the pursuit of these objects, by accomplishing a part of his labour, performed precisely the function of the capitals presently employed by the commercial nations.’ (Lauderdale, p. 120. Notebook, 8a.) ‘It is one of the characteristic and distinguishing traits of the human species to *replace labour in this way* with a capital transformed into machines.’ (p. 120.) (p. 9, Notebook Lauderdale.) ‘It may now be seen that the profit of capitals always arises either because they replace a portion of the work which man must do by hand, or because they accomplish a portion of work which is beyond the personal effort of man, and which he could not perform by himself.’ (p. 119 loc. cit.) Lauderdale polemicizes against Smith and Locke, whose view that labour is the creator of profit, has the following result, according to him: ‘if this idea of capital’s benefits were rigorously correct, then it would follow that it would not be an *original source* of wealth, but rather a derived one; and one could not consider capital as one of the principles of wealth, its *profit being nothing more than a transfer from the worker’s pocket to that of the capitalist.’* (loc. cit. 116, 117.) ‘The profit of capitals always arises either because they *replace* a portion of the work which man must do by hand, or because they accomplish a portion of work which is beyond the personal effort of man, and which he could not perform by himself.’ (p. 119, loc. cit., p. 9b.) ‘It is well to remark that while the capitalist, with the use he makes of his money, saves the class of consumers a certain amount of labour, *he does not substitute for it an equal portion of his own;* which proves that *his capital* performs it, and not he himself.’ (10, Notebook, loc. cit., p. 132.) ‘If Adam Smith, instead of imagining that the effect of a machine is to facilitate labour, or, as he expresses it, to increase the productive power of labour (it is only through a strange confusion of ideas that Mr Smith has been able to assert that the effect of capital is to increase the productive power of labour. With the same logic one could very well claim that *to shorten by half a roundabout path between two points is to double the walker’s speed)* had perceived that the money spent on machinery brings a profit by replacing labour, he would have attributed the origin of profit to the same circumstance.’ (p. 11, p. 137.) ‘Capitals in domestic commerce, whether fixed or circulating, far from serving to set labour in motion, far from increasing its productive power, are, on the contrary, useful and profitable only in two circumstances, either when they obviate the necessity of a portion of the work which man would otherwise have to do with his hands; or when they perform a particular piece of work which man does not have the power to do unaided.' This, says Lauderdale, is not merely a semantic difference. 'The idea that capital sets labour into action, and adds to its productive power, gives rise to the opinion that labour is everywhere proportional to the quantity of existing capitals; that a country's industry is always in proportion to the funds employed: from which it would follow that the increase of capital is the sovereign and unlimited means of increasing wealth. Instead of that, if one admits that capital can have no profitable or useful employment other than to replace a certain work, or to perform it, then one will draw the natural conclusion that the State would gain no benefit whatever from the possession of more capitals than it can employ in doing the work or in substituting for it in the production and fabrication of the things the consumer demands.' (p. 151, 152, pp. 11, 12.) To prove his view that capital is a source *sui generis* of profit and hence of wealth, independently of labour, he points to the surplus profits which the owner of a newly invented machine has before his patent runs out and competition presses down the prices, and concludes then with the words: 'This change of rule for the price does not prevent the benefit' (as regards use value) 'of the machine from coming from a fund of the same nature as that from which it came before the expiration of the patent: *this fund is always that part of a country's revenues which was formerly destined to pay the wages of the labour which the new invention replaces.'* (loc. cit. 125, p. 10b.) By contrast, Ravenstone (IX, 32): 'Machinery can seldom be applied with success to abridge the labours of an individual; more time would be lost in its construction than could be saved by its application. It is only really useful when it acts on great masses, when a single machine can assist the labours of thousands. It is accordingly in the most populous countries where there are most idle men that it is always most abundant. It is not called into action by a scarcity of men, but by the facility with which they are brought together.' (loc. cit.) [78]

'Division of machines into (1) machines employed to produce power; (2)

machines whose purpose is simply to transmit power and to perform the work.' (Babbage, Notebook, p. 10.) [79] '*Factory* signifies the cooperation of several classes of workers, adults and non-adults, watching attentively and assiduously over a system of productive mechanisms, continually kept in action by a central force ... excludes any workshop whose mechanism does not form a continuous system, or which does not depend on a single source of power. Examples of this latter class among textile factories, copper foundries etc. ... In its most rigorous sense, this term conveys the idea of a vast automaton, composed of numerous *mechanical and intellectual organs* operating in concert and without interruption, towards one and the same aim, all these organs being subordinated to a motive force which moves itself.' (Ure, 13.) [80]

The labour process. – Fixed capital. Means of labour. Machine. – *Fixed capital. Transposition of powers of labour into powers of capital both in fixed and in circulating capital. – To what extent* fixed capital (machine) *creates* value. – *Lauderdale. Machine presupposes a mass of workers.*

Capital which consumes itself in the production process, or fixed capital, is the *means of production* in the strict sense. In a broader sense the entire production process and each of its moments, such as circulation – as regards its material side – is only a means of production for capital, for which value alone is the end in itself. Regarded as a physical substance, the raw material itself is a means of production for the product etc.

But the determination that the use value of fixed capital is that which eats itself up in the production process is identical to the proposition that it is used in this process only as a means, and itself exists merely as an agency for the transformation of the raw material into the product. As such a means of production, its use value can be that it is merely the technological condition for the occurrence of the process (the site where the production process proceeds), as with buildings etc., or that it is a direct condition of the action of the means of production proper, like all *matières instrumentales.* Both are in turn only the material presuppositions for the production process generally, or for the employment and maintenance of the means of labour. The latter, however, in the proper sense, serves only within production and for production, and has no other use value.

Originally, when we examined the development of value into capital, the labour process was simply included within capital, and, as regards its physical conditions, its material presence, capital appeared as the totality of the conditions of this process, and correspondingly sorted itself out into certain qualitatively different parts, *material of labour* (this, not raw material, is the correct expression of the concept), *means of labour* and *living labour.* On one side, capital was divided into these three elements in accordance with its material composition; on the other, the *labour process* (or the merging of these elements into each other within the process) was their moving unity, the product their static unity. In this form, the material elements – material of labour, means of labour and living labour – appeared merely as the essential moments of the labour process itself, which capital appropriates. But this material side – or, its character as use value and as real process – did not at all coincide with its formal side. In the latter,

(1) the three elements in which it appears before the exchange with labour capacity, before the real process, appeared merely as quantitatively different portions of itself, as quantities of value of which it, itself, as sum, forms the unity. The physical form, the use value, in which these different portions existed did not in any way alter their formal identity from this side. As far as their formal side was concerned, they appeared only as quantitative subdivisions of capital;

(2) within the process itself, as regards the form, the elements of labour and the two others were distinct only in so far as the latter were specified as constant values, and the former as value-positing. But as far as their distinctness as use values, their material side was concerned, this fell entirely outside the capital’s specific character as form. Now, however, with the distinction between circulating capital (raw material and product) and *fixed capital* (means of labour), the distinctness of the elements as use values is posited simultaneously as a distinction within capital as capital, on its formal side. The relation between the factors, which had been merely quantitative, now appears as a qualitative division within capital itself, and as a determinant of its total movement (turnover). Likewise, the material of labour and the product of

labour, this neutral precipitate of the labour process, are already, as *raw material* and *product,* materially specified no longer as material and product of labour, but rather as the use value of capital itself in different phases.

As long as the means of labour remains a means of labour in the proper sense of the term, such as it is directly, historically, adopted by capital and included in its realization process, it undergoes a merely formal modification, by appearing now as a means of labour not only in regard to its material side, but also at the same time as a particular mode of the presence of capital, determined by its total process – as *fixed capital.* But, once adopted into the production process of capital, the means of labour passes through different metamorphoses, whose culmination is the *machine,* or rather, an *automatic system of machinery* (system of machinery: the *automatic* one is merely its most complete, most adequate form, and alone transforms machinery into a system), set in motion by an automaton, a moving power that moves itself; this automaton consisting of numerous mechanical and intellectual organs, so that the workers themselves are cast merely as its conscious linkages. In the machine, and even more in machinery as an automatic system, the use value, i.e. the material quality of the means of labour, is transformed into an existence adequate to fixed capital and to capital as such; and the form in which it was adopted into the production process of capital, the direct means of labour, is superseded by a form posited by capital itself and corresponding to it. In no way does the machine appear as the individual worker's means of labour. Its distinguishing characteristic is not in the least, as with the means of labour, to transmit the worker's activity to the object; this activity, rather, is posited in such a way that it merely transmits the machine's work, the machine's action, on to the raw material – supervises it and guards against interruptions. Not as with the instrument, which the worker animates and makes into his organ with his skill and strength, and whose handling therefore depends on his virtuosity. Rather, it is the machine which possesses skill and strength in place of the worker, is itself the virtuoso, with a soul of its own in the mechanical laws acting through it; and it consumes coal, oil etc. *(matières instrumentales),* just as the worker consumes food, to keep up its perpetual motion. The worker's activity, reduced to a mere abstraction of activity, is determined and regulated on all sides by the movement of the machinery, and not the opposite. The science which compels the inanimate limbs of the machinery, by their construction, to act purposefully, as an automaton, does not exist in the worker's consciousness, but rather acts upon him through the machine as an alien power, as the power of the machine itself. The appropriation of living labour by objectified labour – of the power or activity which creates value by value existing for-itself – which lies in the concept of capital, is posited, in production resting on machinery, as the character of the production process itself, including its material elements and its material motion. The production process has ceased to be a labour process in the sense of a process dominated by labour as its governing unity. Labour appears, rather, merely as a conscious organ, scattered among the individual living workers at numerous points of the mechanical system; subsumed under the total process of the machinery itself, as itself only a link of the system, whose unity exists not in the living workers, but rather in the living (active) machinery, which confronts his individual, insignificant doings as a mighty organism. In machinery, objectified labour confronts living labour within the labour process itself as the power which rules it; a power which, as the appropriation of living labour, is the form of capital. The transformation of the means of labour into machinery, and of living labour into a mere living accessory of this machinery, as the means of its action, also posits the absorption of the labour process in its material character as a mere moment of the realization process of capital. The increase of the productive force of labour and the greatest possible negation of necessary labour is the necessary tendency of capital, as we have seen. The transformation of the means of labour into machinery is the realization of this tendency. In machinery, objectified labour materially confronts living labour as a ruling power and as an active subsumption of the latter under itself, not only by appropriating it, but in the real production process itself; the relation of capital as value which appropriates value-creating activity is, in fixed capital existing as machinery, posited at the same time as the relation of the use value of capital to the use value of labour capacity; further, the value objectified in machinery appears as a presupposition against which the value-creating power of the individual labour capacity is an infinitesimal, vanishing magnitude; the production in enormous mass quantities which is posited with machinery destroys every connection of the product with the direct need of the producer, and hence with direct use value; it is already posited in the form of the product's production and in the relations in which it is produced that it is produced only as a conveyor of value, and its use value only as condition to that end. In machinery, objectified labour itself appears not only in the form of product or of the product employed as means of labour, but in the form of the force of production itself. The development of the means of labour into machinery is not an accidental moment of capital, but is rather the historical reshaping of the traditional, inherited means of labour into a form adequate to capital. The accumulation of knowledge and of skill, of the general productive forces of the social brain, is thus absorbed into capital, as opposed to labour, and hence appears as an attribute of capital, and more specifically of *fixed capital,* in so far as it enters into the production process as a means of production proper. *Machinery* appears, then, as the most adequate form of *fixed capital,* and fixed capital, in so far as capital's relations with itself are concerned, appears as *the most adequate form of capital* as such. In another respect, however, in so far as fixed capital is condemned to an existence within the confines of a specific use value, it does not correspond to the concept of capital, which, as value, is indifferent to every specific form of use value, and can adopt or shed any of them as equivalent incarnations. In this respect, as regards capital's external relations, it is *circulating capital* which appears as the adequate form of capital, and not fixed capital.

Further, in so far as machinery develops with the accumulation of society's science, of productive force generally, general social labour presents itself not in labour but in capital. The productive force of society is measured in *fixed capital,* exists there in its objective form; and, inversely, the productive force of capital grows with this general progress, which capital appropriates free of charge. This is not the place to go into the development of machinery in detail; rather only in its general aspect; in so far as the *means of labour,* as a physical thing, loses its direct form, becomes *fixed capital,* and confronts the worker physically as *capital.* In machinery, knowledge appears as alien, external to him; and living labour [as] subsumed under self-activating objectified labour. The worker appears as superfluous to the extent that his action is not determined by [capital's] requirements.

NOTEBOOK VII

End of February. March. End of May – Beginning of June 1858

The Chapter on Capital (continuation)

The full development of capital, therefore, takes place – or capital has posited the mode of production corresponding to it – only when the means of labour has not only taken the economic form of *fixed capital,* but has also been suspended in its immediate form, and when *fixed capital* appears as a machine within the production process, opposite labour; and the entire production process appears as not subsumed under the direct skilfulness of the worker, but rather as the technological application of science. [It is,] hence, the tendency of capital to give production a scientific character; direct labour [is] reduced to a mere moment of this process. As with the transformation of value into capital, so does it appear in the further development of capital, that it presupposes a certain given historical development of the productive forces on one side – science too [is] among these productive forces – and, on the other, drives and forces them further onwards.

Thus the quantitative extent and the effectiveness (intensity) to which capital is developed as fixed capital indicate the general degree to which capital is developed as capital, as power over living labour, and to which it has conquered the production process as such. Also, in the sense that it expresses the accumulation of objectified productive forces, and likewise of objectified labour. However, while capital gives itself its adequate form as use value within the production process only in the form of machinery and other material manifestations of fixed capital, such as railways etc. (to which we shall return later), this in no way means that this use value – machinery as such – is capital, or that its existence as machinery is identical with its existence as capital; any more than gold would cease to have use value as gold if it were no longer *money.* Machinery does not lose its use value as soon as it ceases to be capital. While machinery is the most appropriate form of the use value of fixed capital, it does not at all follow that therefore subsumption under the social relation of capital is the most appropriate and ultimate social relation of production for the application of machinery.

To the degree that labour time – the mere quantity of labour – is posited by capital as the sole determinant element, to that degree does direct labour and its quantity disappear as the determinant principle of production – of the creation of use values – and is reduced both quantitatively, to a smaller proportion, and qualitatively, as an, of course, indispensable but subordinate moment, compared to general scientific labour, technological application of natural sciences, on one side, and to the general productive force arising from social combination [*Gliederung*] in total production on the other side – a combination which appears as a natural fruit of social labour (although it is a historic product). Capital thus works towards its own dissolution as the form dominating production.

While, then, in one respect the transformation of the production process from the simple labour process into a scientific process, which subjugates the forces of nature and compels them to work in the service of human needs, appears as a quality of *fixed capital* in contrast to living labour; while individual labour as such has ceased altogether to appear as productive, is productive, rather, only in these common labours which subordinate the forces of nature to themselves, and while this elevation of direct labour into social labour appears as a reduction of individual labour to the level of helplessness in face of the communality [*Gemeinsamkeit*] represented by and concentrated in capital; so does it now appear, in another respect, as a quality of *circulating capital,* to maintain labour in one branch of production by means of *co-existing labour* in another. In small-scale circulation, capital advances the worker the wages which the latter exchanges for products necessary for his consumption. The money he obtains has this power only because others are working alongside him at the same time; and capital can give him claims on alien labour, in the form of money, only because it has appropriated his own labour. This exchange of one's own labour with alien labour appears here not as mediated and determined by the simultaneous existence of the labour of others, but rather by the advance which capital makes. The worker's ability to engage in the exchange of substances necessary for his consumption during production appears as due to an attribute of the part of *circulating capital* which is paid to the worker, and of circulating capital generally. It appears not as an exchange of substances between the simultaneous labour powers, but as the metabolism [*Stoffwechsel*] of capital; as the existence of circulating capital. Thus all powers of labour are transposed into powers of capital; the productive power of labour into fixed capital (posited as external to labour and as existing independently of it (as object [*sachlich*]); and, in circulating capital, the fact that the worker himself has created the conditions for the repetition of his labour, and that the exchange of this, his labour, is mediated by the co-existing labour of others, appears in such a way that capital gives him an advance and posits the simultaneity of the branches of labour. (These last two aspects actually belong to accumulation.) Capital in the form of circulating capital posits itself as mediator between the different workers.

Fixed capital, in its character as means of production, whose most adequate form [is] machinery, produces value, i.e. increases the value of the product, in only two respects: (1) in so far as it *has* value; i.e. is itself the product of labour, a certain quantity of labour in objectified form; (2) in so far as it increases the relation of surplus labour to necessary labour, by enabling labour, through an increase of its productive power, to create a greater mass of the products required for the maintenance of living labour capacity in a shorter time. It is therefore a highly absurd bourgeois assertion that the worker shares with the capitalist, because the latter, with fixed capital (which is, as far as that goes, itself a product of labour, and of *alien labour* merely appropriated by capital) makes labour easier for him (rather, he robs it of all independence and attractive character, by means of the machine), or makes his labour shorter. Capital employs machinery, rather, only to the extent that it enables the worker to work a larger part of his time for capital, to relate to a larger part of his time as time which does not belong to him, to work longer for another. Through this process, the amount of labour necessary for the production of a given object is indeed reduced to a minimum, but only in order to realize a maximum of labour in the maximum number of such objects. The first aspect is important, because capital here – quite unintentionally – reduces human labour, expenditure of energy, to a minimum. This will redound to the benefit of emancipated labour, and is the condition of its emancipation. From what has been said, it is clear how absurd Lauderdale is when he wants to make fixed capital into an independent source of value, independent of labour time. It is such a source only in so far as it is itself objectified labour time, and in so far as it posits surplus labour time. The employment of machinery itself historically presupposes – see above, Ravenstone – superfluous hands. Machinery inserts itself to replace labour only where there is an overflow of labour powers. Only in the imagination of economists does it leap to the aid of the individual worker. It can be effective only with masses of workers, whose concentration relative to capital is one of its historic presuppositions, as we have seen. It enters not in order to replace labour power where this is lacking, but rather in order to reduce massively available labour power to its necessary measure. Machinery enters only where labour capacity is on hand in masses. (Return to this.)

Lauderdale believes himself to have made the great discovery that machinery does not increase the productive power of labour, because it rather replaces the latter, or does what labour cannot do with its own power. It belongs to the concept of capital that the increased productive force of labour is posited rather as the increase of a force [*Kraft*] outside itself, and as labour's own debilitation [*Entkräftung*]. The hand tool makes the worker independent – posits him as proprietor. Machinery – as fixed capital – posits him as dependent, posits him as appropriated. This effect of machinery holds only in so far as it is cast into the role of fixed capital, and this it is only because the worker relates to it as wage-worker, and the active individual generally, as mere worker.

Fixed capital and circulating capital *as two particular kinds of capital. Fixed capital and continuity of the production process. – Machinery and living labour. (Business of inventing)*

While, up to now, fixed capital and circulating capital appeared merely as different passing aspects of capital, they have now hardened into two particular modes of its existence, and fixed capital appears separately alongside circulating capital. They are now two particular kinds of capital. In so far as a capital is examined in a particular branch of production, it appears as divided into these two portions, or splits into these two kinds of capital in certain p[rop]ortions.

The division within the production process, originally between means of labour and material of labour, and finally product of labour, now appears as circulating capital (the last two) and fixed capital [the first]. [1] The split within capital as regards its merely physical aspect has now entered into its form itself, and appears as differentiating it.

From a viewpoint such as Lauderdale's etc., who would like to have capital as such, separately from labour, create *value* and hence also *surplus value* (or profit), fixed capital – namely that whose physical presence or use value is machinery – is the form which gives their superficial fallacies still the greatest semblance of validity. The answer to them, e.g. in *Labour Defended,* [is] that the road-builder may share [profits] with the road-user, but the 'road' itself cannot do so. [2]

Circulating capital – presupposing that it really passes through its different phases – brings about the decrease or increase, the brevity or length of circulation time, the easier or more troublesome completion of the different stages of circulation, a decrease of the surplus value which could be created in a given period of time without these interruptions – either *because the number of reproductions grows smaller,* or because the quantity of *capital continuously engaged in the production process* is reduced. In both cases this is not a reduction of the initial value, but rather a reduction of the rate of its growth. From the moment, however, when fixed capital has developed to a certain extent – and this extent, as we indicated, is the measure of the development of large industry generally – hence fixed capital increases in proportion to the development of large industry's productive forces – it is itself the objectification of these productive forces, as presupposed product – from this instant on, every interruption of the production process acts as a direct reduction of capital itself, of its initial value. The value of fixed capital is reproduced only in so far as it is used up in the production process. Through disuse it loses its use value without its value passing on to the product. Hence, the greater the scale on which fixed capital develops, in the sense in which we regard it here, the more does the *continuity of the production process* or the constant flow of reproduction become an externally compelling condition for the mode of production founded on capital.

In machinery, the appropriation of living labour by capital achieves a direct reality in this respect as well: It is, firstly, the analysis and application of mechanical and chemical laws, arising directly out of science, which enables the machine to perform the same labour as that previously performed by the worker. However, the development of machinery along this path occurs only when large industry has already reached a higher stage, and all the sciences have been pressed into the service of capital; and when, secondly, the available machinery itself already provides great capabilities. Invention then becomes a business, and the application of science to direct production itself becomes a prospect which determines and solicits it. But this is not the road along which machinery, by and large, arose, and even less the road on which it progresses in detail. This road is, rather, dissection [*Analyse*] – through the division of labour, which gradually transforms the workers' operations into more and more mechanical ones, so that at a certain point a mechanism can step into their places. (*See under economy of power.*) Thus, the specific mode of working here appears directly as becoming transferred from the worker to capital in the form of the machine, and his own labour capacity devalued thereby. Hence the workers' struggle against machinery. What was the living worker's activity becomes the activity of the machine. Thus the appropriation of labour by capital confronts the worker in a coarsely sensuous form; capital absorbs labour into itself – 'as though its body were by love possessed'. [3]

Contradiction between the foundation of bourgeois production* (value as measure) *and its development. Machines etc.

The exchange of living labour for objectified labour – i.e. the positing of social labour in the form of the contradiction of capital and wage labour – is the ultimate development of the *value-relation* and of production resting on value. Its presupposition is – and remains – the mass of direct labour time, the quantity of labour employed, as the determinant factor in the production of wealth. But to the degree that large industry develops, the creation of real wealth comes to depend less on labour time and on the amount of labour employed than on the power of the agencies set in motion during labour time, whose 'powerful effectiveness' is itself in turn out of all proportion to the direct labour time spent on their production, but depends rather on the general state of science and on the progress of technology, or the application of this science to production. (The development of this science, especially natural science, and all others with the latter, is itself in turn related to the development of material production.) Agriculture, e.g., becomes merely the application of the science of material metabolism, its regulation for the greatest advantage of the entire body of society. Real wealth manifests itself, rather – and large industry reveals this – in the monstrous disproportion between the labour time applied, and its product, as well as in the qualitative imbalance between labour, reduced to a pure abstraction, and the power of the production process it superintends. Labour no longer appears so much to be included within the production process; rather, the human being comes to relate more as watchman and regulator to the production process itself. (What holds for machinery holds likewise for the combination of human activities and the development of human intercourse.) No longer does the worker insert a modified natural thing [*Naturgegenstand*] as middle link between the object [*Objekt*] and himself; rather, he inserts the process of nature, transformed into an industrial process, as a means between himself and inorganic nature, mastering it. He steps to the side of the production process instead of being its chief actor. In this transformation, it is neither the direct human labour he himself performs, nor the time during which he works, but rather the appropriation of his own general productive power, his understanding of nature and his mastery over it by virtue of his presence as a social body – it is, in a word, the development of the social individual which appears as the great foundation-stone of production and of wealth. The *theft of alien labour time, on which the present wealth is* *based,* appears a miserable foundation in face of this new one, created by large-scale industry itself. As soon as labour in the direct form has ceased to be the great well-spring of wealth, labour time ceases and must cease to be its measure, and hence exchange value [must cease to be the measure] of use value. The *surplus labour of the mass* has ceased to be the condition for the development of general wealth, just as the *non-labour of the few,* for the development of the general powers of the human head. With that, production based on exchange value breaks down, and the direct, material production process is stripped of the form of penury and antithesis. The free development of individualities, and hence not the reduction of necessary labour time so as to posit surplus labour, but rather the general reduction of the necessary labour of society to a minimum, which then corresponds to the artistic, scientific etc. development of the individuals in the time set free, and with the means created, for all of them. Capital itself is the moving contradiction, [in] that it presses to reduce labour time to a minimum, while it posits labour time, on the other side, as sole measure and source of wealth. Hence it diminishes labour time in the necessary form so as to increase it in the superfluous form; hence posits the superfluous in growing measure as a condition – question of life or death – for the necessary. On the one side, then, it calls to life all the powers of science and of nature, as of social combination and of social intercourse, in order to make the creation of wealth independent (relatively) of the labour time employed on it. On the other side, it wants to use labour time as the measuring rod for the giant social forces thereby created, and to confine them within the limits required to maintain the already created value as value. Forces of production and social relations – two different sides of the development of the social individual – appear to capital as mere means, and are merely means for it to produce on its limited foundation. In fact, however, they are the material conditions to blow this foundation sky-high. 'Truly wealthy a nation, when the working day is 6 rather than 12 hours. *Wealth* is not command over surplus labour time' (real wealth), 'but rather, *disposable time* outside that needed in direct production, for *every individual* and the whole society.' (*The Source and Remedy* etc. 1821, p. 6.)

Nature builds no machines, no locomotives, railways, electric telegraphs, self-acting mules etc. These are products of human industry; natural material transformed into organs of the human will over nature, or of human participation in nature. They are *organs of the human brain, created by the human hand;* the power of knowledge, objectified. The development of fixed capital indicates to what degree general social knowledge has become a *direct force of production,* and to what degree, hence, the conditions of the process of social life itself have come under the control of the general intellect and been transformed in accordance with it. To what degree the powers of social production have been produced, not only in the form of knowledge, but also as immediate organs of social practice, of the real life process.

Significance of the development of fixed capital *(for the development of capital generally). Relation between the creation of fixed capital and circulating capital. Disposable time. To create it, chief role of capital. Contradictory form of the same in capital. – Productivity of labour and production of fixed capital.* (The Source and Remedy.) – *Use and consume:* Economist. *Durability of fixed capital*

The development of fixed capital indicates in still another respect the degree of development of wealth generally, or of capital. The aim of production oriented directly towards use value, as well as of that directly oriented towards exchange value, is the product itself, destined for consumption. The part of production which is oriented towards the production of fixed capital does not produce direct objects of individual gratification, nor direct exchange values; at least not directly realizable exchange values. *Hence, only when a certain degree of productivity has already been reached – so that a part of production time is sufficient for immediate production – can an increasingly large part be applied to the production of the means of production.* This requires that society be able to wait; that a large part of the wealth already created can be withdrawn both from immediate consumption and from production for immediate consumption, in order to employ this part for labour which is *not immediately productive* (within the material production process itself). This requires a certain level of productivity and of relative overabundance, and, more specifically, a level directly related to the transformation of circulating capital into fixed capital. As the *magnitude of relative surplus labour depends on the productivity of necessary labour, so does the magnitude of labour time* – living as well as objectified – *employed on the production of fixed capital depend on the productivity of the labour time spent in the direct production of products. Surplus population* (from this standpoint), as well as *surplus production,* is a condition for this. That is, the output of the time employed in direct production must be larger, relatively, than is directly required for the reproduction of the capital employed in these branches of industry. The *smaller* the direct fruits borne by *fixed capital,* the less it intervenes in the *direct production process,* the greater must be this relative *surplus population and surplus production;* thus, more to build railways, canals, aqueducts, telegraphs etc. than to build the machinery directly active in the direct production process. Hence – a subject to which we will return later – in the constant under- and over-production of modern industry – constant fluctuations and convulsions arise from the disproportion, when sometimes too little, then again too much circulating capital is transformed into fixed capital.

<*The creation of a large quantity of disposable time* apart from necessary labour time for society generally and each of its members (i.e. room for the development of the individuals' full productive forces, hence those of society also), this creation of not-labour time appears in the stage of capital, as of all earlier ones, as not-labour time, free time, for a few. What capital adds is that it increases the surplus labour time of the mass by all the means of art and science, because its wealth consists directly in the appropriation of surplus labour time; since *value directly its purpose,* not use value. It is thus, despite itself, instrumental in creating the means of social disposable time, in order to reduce labour time for the whole society to a diminishing minimum, and thus to free everyone's time for their own development. But its tendency always, on the one side, *to create disposable time, on the other, to convert it into surplus labour.* If it succeeds too well at the first, then it suffers from surplus production, and then necessary labour is interrupted, because *no surplus labour can be realized by capital.* The more this contradiction develops, the more does it become evident that the growth of the forces of production can no longer be bound up with the appropriation of alien labour, but that the mass of

workers must themselves appropriate their own surplus labour. Once they have done so – and *disposable time* thereby ceases to have an *antithetical* existence – then, on one side, necessary labour time will be measured by the needs of the social individual, and, on the other, the development of the power of social production will grow so rapidly that, even though production is now calculated for the wealth of all, *disposable time* will grow for all. For real wealth is the developed productive power of all individuals. The measure of wealth is then not any longer, in any way, labour time, but rather disposable time. *Labour time as the measure of value* posits wealth itself as founded on poverty, and disposable time as existing *in and because of the antithesis to surplus labour time;* or, the positing of an individual's entire time as labour time, and his degradation therefore to mere worker, subsumption under labour. *The most developed machinery thus forces the worker to work longer than the savage does, or than he himself did with the simplest, crudest tools.>*

'If the entire labour of a country were sufficient only to raise the support of the whole population, there would be no *surplus labour,* consequently nothing that could be allowed to accumulate as capital. If in one year the people raises enough for the support of two years, one year's consumption must perish, or for one year men must cease from productive labour. But the *possessors of [the] surplus produce or capital …* employ people upon *something not directly and immediately productive,* e.g. in the erection of machinery. So it goes on.' (*The Source and Remedy of the National Difficulties,* p. 4.)

<As the basis on which large industry rests, the appropriation of alien labour time, ceases, with its development, to make up or to create wealth, so does *direct labour* as such cease to be the basis of production, since, in one respect, it is transformed more into a supervisory and regulatory activity; but then also because the product ceases to be the product of isolated direct labour, and the *combination* of social activity appears, rather, as the producer. 'As soon as the division of labour is developed, almost every piece of work done by a single individual is a part of a whole, *having no value or utility of itself. There is nothing on which the labourer can seize: this is my produce, this I will keep to myself.'* (*Labour Defended,* p. 25, 1, 2, XI.) In direct exchange, individual direct labour appears as realized in a particular product or

part of the product, and its communal, social character – its character as objectification of general labour and satisfaction of the general need – as posited through exchange alone. In the production process of large-scale industry, by contrast, just as the conquest of the forces of nature by the social intellect is the precondition of the productive power of the means of labour as developed into the automatic process, on one side, so, on the other, is *the labour of the individual in its direct presence posited as suspended individual, i.e. as social, labour. Thus the other basis of this mode of production falls away.>*

The labour time employed in the production of fixed capital relates to that employed in the production of circulating capital, within the production process of capital itself, as does *surplus labour time to necessary* labour time. To the degree that production aimed at the satisfaction of immediate need becomes more productive, a greater part of production can be directed towards the need of production itself, or the production of means of production. In so far as the production of *fixed capital,* even in its physical aspect, is directed immediately not towards the production of direct use values, or towards the production of values required for the direct reproduction of capital – i.e. those which themselves in turn represent use value in the value-creation process – but rather towards the production of the means of value creation, that is, not towards value as an immediate object, but rather towards value creation, towards the means of realization, as an immediate object of production – the production of value posited physically in the object of production itself, as the aim of production, the objectification of productive force, the value-producing power of capital – to that extent, it is in the production of *fixed capital that capital posits itself as end-in-itself* and appears active as capital, *to a higher power than it does in the production of circulating capital.* Hence, in this respect as well, the dimension already possessed by fixed capital, which its production occupies within total production, is the measuring rod *of the development* of wealth founded on the mode of production of capital.

‘The number of workers depends as much on *circulating capital* as it depends on the quantity *of products of co-existing labour,* which labourers are allowed to consume.’ *(Labour Defended,* p. 20.)

In all the excerpts cited above from various economists fixed capital is regarded as the part of capital which is locked into the production process. ‘Floating capital is consumed; fixed capital is merely used in the great process of production.’ *(Economist,* VI, 1.) [4] This wrong, and holds only for the part of circulating capital which is itself consumed by the fixed capital, the *matières instrumentales.* The only thing consumed ‘in the great process of production’, if this means the immediate production process, is *fixed capital.* Consumption within the production process is, however, in fact *use, wearing-out.* Furthermore, the *greater durability of fixed capital* must not be conceived as a purely physical quality. The iron and the wood which make up the bed I sleep in, or the stones making up the house I live in, or the marble statue which decorates a palace, are just as durable as iron and wood etc. used for machinery. But *durability* is a condition for the instrument, the means of production, not only on the technical ground that metals etc. are the chief material of all machinery, but rather because the instrument is destined to play the same role constantly in repeated processes of production. Its durability as means of production is a required quality of its use value. The more often it must be replaced, the costlier it is; the larger the part of capital which would have to be spent on it uselessly. Its durability is its existence as means of production. Its duration is an increase of its productive force. With circulating capital, by contrast, in so far as it is not transformed into fixed capital, durability is in no way connected with the act of production itself and is therefore not a conceptually posited moment. The fact that among the articles thrown into the consumption fund there are some which are in turn characterized as *fixed capital* because they are consumed slowly, and can be consumed by many individuals in series, is connected with further determinations (renting rather than buying, interest etc.) with which we are not yet here concerned.

‘Since the general introduction of soulless mechanism in British manufactures, people have with rare exceptions been treated as a secondary and subordinate machine, and far more attention has been given to the perfection of the raw materials of wood and metals than to those of body and spirit.’ (p. 31. Robert Owen: *Essays on the Formation of the Human Character,* 1840, London.)

Real saving – economy – = saving of labour time = development of productive force. Suspension of the contradiction between free time and labour time. – True conception of the process of social production

<Real economy – saving – consists of the saving of labour time (minimum (and minimization) of production costs); but this saving identical with development of the productive force. Hence in no way *abstinence from consumption,* but rather the development of power, of capabilities of production, and hence both of the capabilities as well as the means of consumption. The capability to consume is a condition of consumption, hence its primary means, and this capability is the development of an individual potential, a force of production. The saving of labour time [is] equal to an increase of free time, i.e. time for the full development of the individual, which in turn reacts back upon the productive power of labour as itself the greatest productive power. From the standpoint of the direct production process it can be regarded as the production of *fixed capital,* this fixed capital being man himself. It goes without saying, by the way, that direct labour time itself cannot remain in the abstract antithesis to free time in which it appears from the perspective of bourgeois economy. Labour cannot become play, as Fourier would like, [5] although it remains his great contribution to have expressed the suspension not of distribution, but of the mode of production itself, in a higher form, as the ultimate object. Free time – which is both idle time and time for higher activity – has naturally transformed its possessor into a different subject, and he then enters into the direct production process as this different subject. This process is then both discipline, as regards the human being in the process of becoming; and, at the same time, practice [*Ausübung*], experimental science, materially creative and objectifying science, as regards the human being who has become, in whose head exists the accumulated knowledge of society. For both, in so far as labour requires practical use of the hands and free bodily movement, as in agriculture, at the same time exercise.

As the system of bourgeois economy has developed for us only by degrees, so too its negation, which is its ultimate result. We are still concerned now with the direct production process. When we consider bourgeois society in the long view and as a whole, then the final result of the process of social production always appears as the society itself, i.e. the human being itself in its social relations. Everything that has a fixed form, such as the product etc., appears as merely a moment, a vanishing moment, in this movement. The direct production process itself here appears only as a moment. The conditions and objectifications of the process are themselves equally moments of it, and its only subjects are the individuals, but individuals in mutual relationships, which they equally reproduce and produce anew. The constant process of their own movement, in which they renew themselves even as they renew the world of wealth they create.>

Owen's *historical conception of industrial* (capitalist) *production*

(In his *Six Lectures Delivered at Manchester,* 1837, Owen speaks about the difference which capital, by its very growth (and widespread appearance, and it obtains the latter only with large-scale industry, which is connected with the development of fixed capital), creates between workers and capitalists; but formulates the development of capital as a *necessary condition* for the recreation of society, and recounts about himself: 'It was by being gradually trained to create and conduct some of these large' (manufacturing) 'establishments, that your lecturer' (Owen himself) 'was taught to understand the great errors and disadvantages of the past and present attempts to ameliorate the character and situation of his fellow beings.' (p. 58.) We here put down the entire excerpt, to be used on another occasion.

'The producers of developed wealth can be divided into workers in soft and workers in hard materials, under the immediate direction generally of masters whose object it is to make money through the labour of those they employ. Before the introduction of the chemical and mechanical manufacturing system, operations were carried out on a limited scale; there were many small masters, each with a few day-labourers, who expected in due time to become small masters themselves. They usually ate at the same table and lived together; a spirit and feeling of equality reigned among them. Since the period when scientific power began by and large to be employed in the business of manufacturing, a gradual change has taken place in this regard. Almost all manufactures, to be successful, must now be carried out extensively and with a great capital; small masters with small capitals have only little chance of success, particularly in the manufactures of soft materials, such as cotton, wool, flax etc.; and it is indeed evident now, that so long as the present classification of society and the mode of directing business life should endure, the small masters will be increasingly displaced by those who possess great capitals, and that the former relatively happier equality among the producers must give way to the greatest inequality between master and worker, such as has never before occurred in the history of mankind. The large capitalist is now elevated to the position of a commanding lord, treating the health, the life and death, indirectly, of his slaves, as he likes. He obtains this power through combination with other great capitalists, engaged in the same interest with himself, and thus effectively bends to his purpose those he employs. The large capitalist now swims in wealth, whose proper use he has not been taught and does not know. Through his wealth, he has gained power. His wealth and his power blind his reason; and when he oppresses altogether grievously, he believes he is bestowing favours ... His servants, as they are called, his slaves in fact, are reduced to the most hopeless degradation; the majority robbed of health, of domestic comfort, of the leisure and healthy open-air pleasures of earlier days. Through excessive exhaustion of their powers, brought about by lengthy, drawn-out monotonous occupations, they are seduced into habits of intemperance, and made unfit for thinking or reflection. They can have no physical, intellectual or moral amusements other than of the worst sort; all real pleasures of life are far distant from them. The life which a very large part of the workers lead under the present system is, in a word, not worth having. But the individuals are not to blame for the changes of which these are the result; *they proceed in the regular order of nature and are preparatory and necessary stages towards the great and important social revolution* now in progress. Without great capitals no great establishments can be founded; men cannot be brought to understand the practicability of effecting new combinations, in order to ensure a superior character to all and the production of more annual wealth than can be consumed by all; and that wealth, too, should be of a higher kind than that hitherto generally produced.' (loc. cit. 56, 57.) 'It is this new chemical and mechanical manufacturing system which now expands human abilities, and prepares men to understand and to adopt other principles and practices, and thus to effect the most beneficial change in affairs which the world has yet known. And it is this new manufacturing system which now creates the necessity for another and higher classification of society.’ (loc. cit. 58.))

Capital and value of natural agencies. – Scope of fixed capital indicates the level of capitalist production. – Determination of raw material, product, instrument of production, consumption. – Is money fixed capital or circulating capital? – Fixed capital and circulating capital in regard to individual consumption

We remarked earlier that the force of production (fixed capital) only has value, hence only imparts value, in so far as it is itself produced, itself a given quantity of objectified labour time. But now natural agencies enter in, such as water, land (this notably), mines etc., which are appropriated, hence possess exchange value, and hence come as values into the calculation of production costs. This is, in a word, the entry of landed property (which includes earth, mines, water). The value of means of production which are not the product of labour does not belong here yet, since it does not arise out of the examination of capital itself. They appear for capital, initially, as given, historic presupposition. And we leave them as such, here. Only the form of landed property – or of natural agencies as value-determining magnitudes – modified to correspond to capital belongs within the examination of the system of bourgeois economy. It does not affect the examination of capital at the point we have so far reached, to regard land etc. as a form of fixed capital.

Since *fixed capital,* in the sense of a produced production force, as agency of production, increases the mass of use values created in a given time, it cannot grow without the raw material it works on also growing (in manufacturing industry. In the extractive industries, such as fishery, mining, labour merely consists in overpowering the obstacles in the way of the seizure and appropriation of the raw products or primary products. There is no raw material to be worked up for production; rather, the existing raw product is appropriated. By contrast, in agriculture the raw material is the earth itself; seed the circulating capital etc.). Its employment on a larger scale thus presupposes expansion of the part of circulating capital consisting of raw materials; hence growth of capital generally. It likewise presupposes (relative) decrease of the portion of capital exchanged for living labour.

In *fixed capital,* capital exists materially, too, not only as objectified labour, destined to serve as the means of new labour, but rather as value, whose use value is to create new values. The existence of fixed capital is therefore κατ᾽ ἐξοχήν its existence as productive capital. Hence the stage of development reached by the mode of production based on capital – or the extent to which capital itself is already presupposed as the condition of its own production, has presupposed itself – is measured by the existing scope of fixed capital; not only by its quantity, but just as much by its quality.

Finally: in *fixed capital,* the social productivity of labour [is] posited as a property inherent in capital; *including the scientific power as well as the combination of social powers within the production process, and finally, the skill transposed from direct labour into the machine, into the dead productive force. In circulating capital,* by contrast, it is the exchange of labours, of the different branches of labour, their interlacing and system-forming quality, the co-existence of productive labour, which appear as *property of capital.* *

* The determinations of raw material, product, instrument of production, change according to the role which the use values play in the production process itself. What may be regarded as a mere raw material (certainly not agricultural products, which are all reproduced, and not only reproduced in their original form, but also modified in their natural being itself to correspond to human needs. Quote from Hodges etc. [6] The products of purely extractive industry such as e.g. coal, metals, are themselves the result of labour, not only to bring them to light, but also in order to give them the form, as with metals, in which they can serve as raw materials for industry. But they are not reproduced, since we do not yet know how to create metals) is itself the product of labour. The product of one industry is the raw material for another and vice versa. The instrument of production itself is the product of one industry, and serves as instrument of production only in the other. One industry's waste is the raw material of the other. In agriculture, a part of the product (seed, cattle etc.) itself appears as raw material for the same industry; hence, like fixed capital, it never leaves the production process; the portion of the agricultural products destined for animal feed can be regarded as *matière instrumentale;* but seed is reproduced in the production process, while the instrument as such is consumed in it. Could not seed, considering that it always

> remains within the production process, like draught animals, be regarded as fixed capital, like draught animals? No; otherwise all raw materials would have to be so regarded. As raw material it is always comprised within the production process. Finally, products entering into direct consumption in turn come out of consumption as raw materials for production, fertilizer in the process of nature etc., paper out of rags etc.; but secondly, their consumption reproduces the individual himself in a specific mode of being, not only in his immediate quality of being alive, and in specific social relations. So that the ultimate appropriation by individuals taking place in the consumption process reproduces them in the original relations in which they move within the production process and towards each other; reproduces them in their social being, and hence reproduces their social being – society – which appears as much the subject as the result of this great total process.

Fourthly:

We have now to examine the other relations of fixed capital and circulating capital.

We said above that the social relation between different labours is posited as a property of capital in *circulating capital,* as the social productive power of labour in fixed capital.

'The circulating capital of a nation is: money, necessaries of life, raw materials, and finished products.' (Adam Smith, tome II, p. 218.) Smith is in a quandary whether he should call money circulating or fixed capital. In so far as it always serves merely as instrument of circulation, which is itself a moment of the total reproduction process, it is *fixed capital* – as instrument of circulation. But its use value itself is only to circulate and never to be absorbed either into the production process proper nor into individual consumption. It is the part of capital constantly fixed in the circulation phase, and in this respect it is the most perfect form of circulating capital; in the other respect, because it is fixed as an instrument, it is *fixed capital.*

In so far as a distinction between *fixed capital and circulating capital* enters in from the perspective of individual consumption, this is already given in the fact that *fixed capital* does not enter into circulation as use value. (A part of the seed in agriculture does enter into circulation as use value, because it multiplies itself.) This non-entry-into-circulation supposes that it does not become the object of individual consumption.

Turnover time of capital consisting of fixed capital and circulating capital. Reproduction time of fixed capital. With circulating capital, the only requirement is that the interruption should be not so great as to ruin its use value. With fixed capital, continuity of production absolutely necessary etc. – Unit of labour time the day; for circulating capital, the year. Longer total period as unit with the entry of fixed capital. – Industrial cycle. – Circulation of fixed capital. – The so-called risk. – All parts of capital yield an equal profit – false. **Ricardo** ***etc. – The same commodity sometimes fixed capital, sometimes circulating capital. – Sale of capital as capital. – Fixed capital which enters into circulation as use value.*** **– Every moment which a presupposition of production, at the same time its result. Reproduction of its own conditions.** ***Reproduction of capital as fixed capital and circulating capital***

‘*Fixed capital’* serves over and over again for the same operation, ‘and by how much larger has been the range of these iterations, by so much [the] more intensely is the tool, engine, or machinery, entitled to the denomination of fixed’. (De Quincey, X, 4.) [7] If a capital consists of £10,000, of which 5,000 is fixed and 5,000 circulating; the latter turns over 1 time in 1 year, the former 1 time in 5 years; then 5,000 turn over, or 1/2 of the total capital, 1 time in one year. During the same year, 1/5 of the fixed capital or £1,000 turn over; hence in 1 year £6,000 or 3/5 of the total capital turn over. Hence 1/5 of the total capital turns over in 12/3 months and the total capital, in (12 × 5)/3 months, in 60/3 = 20 months = 1 year and 8 months. In 20 months the total capital of £10,000 is turned over, although the fixed capital is replaced only in 5 years. This turnover time holds, however, only for the repetition of the production process and thus for the creation of surplus value; not for the reproduction of the capital itself. If the capital begins the process anew less frequently – returns from circulation into the form of fixed capital – then it returns all the more often into the form of circulating capital. But the capital itself is not replaced thereby. So with the circulating capital itself. If a capital of 100 returns 4 times a year and hence brings in 20%, like a capital of 400 which circulates only once, then the capital remains 100 at the end of the year as at the beginning, and the other capital remains 400, although it has effected a production of use values and a positing of surplus value equal to a 4 times larger capital. The fact that the velocity of turnover here substitutes for the magnitude of the capital shows strikingly that it is only the amount of surplus labour set into motion, and of labour generally, which determines the creation of value as well as the creation of surplus value, and not the magnitude of the capital for itself. The capital of 100 has, during the year, set in motion successively as much labour as one of 400, and hence created the same surplus value.

But the issue here is this. In the above example, the circulating capital of 5,000 first returns in the middle of the first year; then at the end of the second half; in the middle of the second; in the second half of the second (in the first 4 months) £3,333 2/6 of it have returned and the rest will have come back at the end of this half year.

But, of the fixed capital, only 1/5 was returned in the first year, 1/5 in the second. At the end of the first year, the owner has on hand £6,000; at the end of the second, 7,000; the third, 8,000; the fourth, 9,000; the fifth, 10,000. Only at the end of the fifth is he again in possession of his total capital, with which he began the production process; although *in the creation of surplus value his capital acted as if it had wholly turned over in 20 months; thus the total capital itself is only reproduced in 5 years. The former aspect of turnover important for the relation of its realization;* the latter, however, brings in a new relation which does not take place with circulating capital at all. *Since circulating capital is completely absorbed into circulation and returns from it as a whole, it follows that it is reproduced as capital* as *many times as it is realized as surplus value* or as surplus capital. But since fixed capital never enters circulation as a use value, and enters it as value only to the extent that it is consumed as a use value, it follows that it is by no means reproduced as soon as the *surplus value determined by the average turnover time of the total capital is posited.* The turnover of the circulating capital must take place 10 times in the 5 years before the fixed capital is reproduced; i.e. the period of the revulsions of circulating capital must be repeated 10 times while that of fixed capital is repeated once, and the *total average turnover of the capital – 20 months – has to be repeated 2 times before the fixed capital is reproduced.* Hence, the larger is the part of the capital consisting of fixed capital – i.e. the more capital acts in the mode of production corresponding to it, with great employment of produced productive force – and the more durable the fixed capital is, i.e. the longer its reproduction time, the more its use value corresponds to its specific economic role – the more often must the part of capital which is determined as circulating *repeat the period of its turnover, and the longer is the total time the capital requires for the achievement of its total circulation.* Hence the *continuity* of production becomes an external necessity for capital with the development of that portion of it which is determined as fixed capital. For circulating capital, *an interruption, if it does not last so long as to ruin its use value, is only an interruption in the creation of surplus value. But with fixed capital, the interruption,* in so far as in the meantime its use value is necessarily destroyed relatively unproductively, i.e. without replacing itself as value, is the destruction of its original value itself. Hence the continuity of the production process which corresponds to the concept of capital is posited as *conditio sine qua [non]* for its maintenance only with the development of fixed capital; hence likewise the continuity and the constant growth of consumption.

This is No. I. But No. II, the formal side, even more important. The total time in which we measured the return of capital was the year, while the time unit in which we measure labour is the day. We did [so] firstly because the year is more or less the natural reproduction time, or duration of the production phase, for the reproduction of the largest part of the vegetable raw materials used in industry. The turnover of circulating capital was determined, therefore, by the number of turnovers in the total time of a year. In fact, the circulating capital begins its reproduction at the end of each turnover, and while the number of turnovers during the year affects the total value, and the fate it encounters during each turnover appears as a determinant of the conditions under which it begins reproduction anew, yet each of them for itself is a complete lifespan for the circulating capital. As soon as capital is transformed back into money, it can transform itself e.g. into conditions of production other than the original ones, throw itself from one branch of production into another one, so that *reproduction, regarded materially, is not repeated in the same form.*

The introduction of fixed capital changes this; and neither the turnover time of capital, nor the unit in which their number is measured, the year, henceforth appear as the measure of time for the motion of capital. This unit is now determined, rather, by the *reproduction time* required for fixed capital, and hence the total circulation time it needs to enter into circulation as value, and to come back from it in the totality of its value. The reproduction of the circulating capital must *also proceed in the same material form* during this whole time, and the number of its necessary turnovers, i.e. *the turnovers necessary for the reproduction of the original capital, is distributed over a longer or shorter series of years.* Hence a longer *total period* is posited as the unit in which its turnovers are measured, and their *repetition* is now not merely externally, but rather necessarily connected with this unit. According to Babbage, the average reproduction of machinery in England 5 years; [8] the real one hence perhaps 10 years. There can be no doubt whatever that the cycle which industry has passed through since the development of fixed capital on a large scale, at more or less 10-yearly intervals, is connected with this *total reproduction phase of capital.* We shall find other determinant causes as well. But this is one of them. There were good and bad times for industry before, too, as well as for harvests (agriculture). But the industrial cycle of a number of years, divided into characteristic periods, epochs, is peculiar to large-scale industry.

Now the new distinction, No. III, appears.

Circulating capital was ejected from the production process in the form of the product, of the newly created use value, and thrown wholly into circulation; when transformed back into money, the entire value of the product (the entire labour time objectified in it, necessary and surplus labour time) was realized, and thereby the surplus value realized and all conditions of reproduction fulfilled. With the realization of the price of the commodity, all these conditions were fulfilled, and the process could begin anew. This holds, however, only for that part of the circulating capital which entered into large-scale circulation. As to the other portion of it, which continuously accompanies the process of production itself, the circulation of that part of it which is transformed into wages, it naturally depends on whether the labour is used for the production of fixed capital or of circulating capital whether these wages themselves are replaced by a use value entering into circulation or not.

Fixed capital, by contrast, does not itself circulate as a use value, but rather enters as value into the manufactured raw material (in manufactures and agriculture) or into the directly extracted raw material (mining industry etc.) only to the extent that it is used up as use value in the production process. Fixed capital in its developed form hence only returns in a cycle of years which embraces a series of turnovers of circulating capital. It is not at once exchanged as product for money, in such a way that its reproduction process might coincide with the turnovers of circulating capital. It enters into the price of the product only in successive bits, and hence returns as value only successively. *It returns fragmentarily over longer periods, while circulating capital circulates wholly in shorter periods.* To the extent that fixed capital remains as such, [it] does not return, because it does not enter into circulation; to the extent that it enters into circulation, it no longer remains as fixed capital, but rather forms an ideal value-component of the circulating capital. It returns in principle only to the extent that it *transposes itself directly or indirectly into the product, hence into circulating capital.* Because it is not a direct use value for consumption, it does not enter into circulation as use value.

This different kind of return of fixed and circulating capital will appear significant later as the difference between selling and renting, annuity, interest and profit, rent in its different forms, and profit; and the incomprehension of this *merely formal* distinction has led Proudhon and his gang to the most confused conclusions; as we shall see. [9] In its observations on the last crisis, the *Economist* reduces the whole difference between fixed capital and circulating capital to the 'resale of articles within *a short period and at a profit'* (*Economist* No. 754, 6 Feb. 1858) and 'production of a revenue large enough to provide for *expenses,* risk, *wear and tear,* and the market rate of interest'. * The shorter return through the sale of the whole article, and the merely annual return of a part of the fixed capital, analysed above. As to profit – merchant's profit does not concern us here – each part of the circulating capital which leaves and returns to the production process, i.e. contains objectified labour (the value of the advances), necessary labour (the value of wages) and surplus labour – brings profit as soon as it passes fully through circulation, because the surplus labour which the product contains is realized with it. But it is neither the circulating capital nor the fixed capital which create the profit, but rather the appropriation of alien labour which both of them mediate, hence at bottom only the part of circulating capital which enters into small-scale circulation. This profit is realized in practice, however, only through the entry of capital into circulation, hence only in its form as circulating capital, never in its form as fixed capital. But what the economist here understands by fixed capital is – as far as revenues from it are concerned – the form of fixed capital in which it does not directly enter into the production process as machinery, but rather in railways, buildings, agricultural improvements, drainings etc., † where, hence, the realization of the value and surplus value contained in it appears in the form of an annuity, where interest represents the surplus value and the annuity the successive return of the value advanced. This is therefore not in fact a case (although it is the case with agricultural improvements) of fixed capital entering into circulation as value by forming a part of the product, but rather of the sale of fixed capital in the form of its use value. It is here sold not all at once, but as an annuity. Now, it is clear, firstly, that some forms of fixed capital figure initially as circulating capital, and become fixed capital only when they become fixed in the production process; e.g. the circulating products of a machine-maker are machines just as those of a cotton-weaver are calico, and they enter into circulation in just the same way, for him. For him they are circulating capital; for the manufacturer who uses them in the production process, fixed capital; because product for the former, and instrument of production only for the latter. Likewise even houses, despite their immovability, are circulating capital for the building-trade; for him who buys them to rent them out again, or to use them as buildings for production, they are fixed capital. Now in so far as fixed capital itself circulates as use value, i.e. is sold, changes hands, we shall speak of it further, below.

* Risk, which plays a role for the economists in the determination of profit – it can obviously play none in the surplus gain, because the creation of surplus value is not increased thereby, and possible that capital incurs risk in the *realization* of this surplus value – is the danger that the capital does not pass through the different phases of circulation, or remains fixated in one of them. We have seen that the surplus gain is part of the production costs, not of the capital, but of the product. The necessity for capital to realize this surplus gain or a part of it confronts it as a double external compulsion. As soon as profit and interest become separated, so that the industrial capitalist must pay interest, a portion of the surplus gain is *cost of production* from capital's viewpoint, i.e. belongs itself among his outlays. In another respect, it is the

> average assecurance which it gives itself in order to cover the risk of devaluation which it runs in the metamorphoses of the total process. A part of the surplus gain appears to the capitalist only as a compensation for the risk he runs so as to make more money; a risk which can lead to the loss of the presupposed value itself. In this form, the necessity of realizing the surplus gain appears to him as means to ensure its reproduction. Both relations, of course, do not determine the surplus value, but rather make its positing appear as an external necessity for capital, and not only as the satisfaction of its tendency to seek riches.
>
> ‡ We are not concerned here with the illusion that *all parts of capital equally bring a profit,* an illusion arising out of the division of the surplus value into average portions, independently of the relations of the component parts of capital as circulating and fixed, and the part of it transformed into living labour. Because Ricardo half shares this illusion, he considers the influence of the proportions of fixed and circulating capital from the start of his determination of value as such, and the reverend parson Malthus stupidly and simple-mindedly speaks of the profits accruing to fixed capital, as if capital grew organically by some power of nature.

But the viewpoint that capital is sold as capital – whether as money or in the form of fixed capital – is obviously not relevant here, where we are considering circulation as the movement of capital in which it posits itself in its various conceptually specific moments. Productive capital becomes product, commodity, money, and is transformed back into the conditions of production. It remains capital in each of these forms, and it becomes capital only by realizing itself as such. So long as it remains in one of these phases, it is fixed as commodity capital, money capital, or industrial capital. But each of these phases forms only one moment of its movement, and in the form from which it must propel itself to pass over into another phase it ceases to be capital. If it rejects itself as commodity and becomes money, or vice versa, then it does not exist as capital in the rejected form, but rather in the newly reached one. Of course, the rejected form can in turn become the form of another capital, or it can be the direct form of the consumable product. But this does not concern us and does not concern capital as far as the course it traces out in its internal circulation is concerned. Rather, it rejects each of the forms as its not-capital-being, so as to assume them again later. But if capital is lent out as money, as land and soil, house etc., then it becomes a commodity *as capital,* or, the commodity put into circulation is *capital as capital.* This to be further pursued in the next section.

What is paid for in the transposition of the commodity into money, as far as the part of the price which is the value of part of the fixed capital is concerned, is the part required for its partial reproduction, the part worn out and used up in the production process. What the buyer pays, then, is the use or wear of the fixed capital, in so far as it is itself value, objectified labour. Since this wear takes place successively, he pays it in portions in the product, whereas in the price he pays for the product he replaces the whole value of the fractional part of the raw material contained in the product. The worn-out, used-up fractional part of fixed capital is paid for not only successively, but also by a mass of buyers simultaneously, in relation as they buy products. Since capital appears in the first half of its circulation as C and the buyer as M, since its aim is value while the buyer's is use (whether in turn productive, no matter here, where we are examining only the formal aspect such as it appears towards capital in its circulation), it follows that the relation of the buyer to the product is that of the consumer generally. Indirectly, then, in all commodities the buyer successively and bit by bit pays for the wear and use of fixed capital, even though the latter does not enter into circulation as use value. But there are forms of fixed capital where he pays directly for its use value – as with means of communication, transport etc. In all these cases the fixed capital in fact never leaves the production process, as with railways etc. But while it serves for some as means of communication within the production process itself, to bring the product to market, and for the producers themselves [as] means of circulation, it can serve others as means of consumption, as use value, for holiday travel, etc. Regarded as a means of production, it distinguishes itself from machinery etc. here in that it is used up by various capitals at the same time, as a common condition for their production and circulation. (We are not yet concerned with consumption as such here.) It does not appear as locked within a particular production process, but rather as the connecting artery of a mass of such production processes of particular capitals, who use it up only in portions. In contrast to all these particular capitals and their particular production processes, then, fixed capital is here cast as the product of a particular branch of production separate from them, in which, however, it is not sold by one producer as circulating capital and bought by another as fixed capital, as with machinery, but, rather, in which it can be sold only in the form of fixed capital itself. Then its successive return, hidden in the commodity, becomes apparent. But this fixed capital then also includes the surplus value, since it is itself a sold product (for the industrialist, the machine he uses is not a product), hence the return of interest and profit, if any. Since it can be consumed in the same common and successive form, can be use value for direct consumption, it follows that its sale – not as an instrument of production but as a commodity generally – also appears in the same form. But in so far as it is sold as an instrument of production – a machine is *sold* as a mere commodity and only becomes an instrument of production in the industrial process – i.e. as its sale directly coincides with its use in the general social production process, this is a determination which has no place within the examination of the simple circulation of capital. In the latter, fixed capital, in so far as it enters as an agency of production, appears as a presupposition of the production process, not as its result. It can therefore only be a matter of the replacement of its value, in which no surplus value for the user is included. What is rather the case is that *he* has paid this surplus value to the machine-maker. Railways, however, or buildings rented for production, are *simultaneously* instruments of production, and are simultaneously realized by their seller as product, as capital.

Since each moment which appears as presupposition of production is at the same time its result – in that it reproduces its own conditions – the original division of the capital within the production process now appears in such a way that the production process divides into three production processes, in which different portions of the capital – which now also appear as particular capitals – are at work. (Here we can still assume a form in which one capital is at work, because we are examining capital *as such,* and this way of looking at it simplifies what needs to be said about the proportion of these different kinds.) The capital is annually reproduced in different and changing portions as raw material, as product, and as means of production; in a word, as fixed capital and as circulating capital. The minimum presupposition which appears in all of these production processes is the part of circulating capital destined for exchange with labouring capacity and for the maintenance and consumption of the machinery or the instrument, and the means of production. In purely extractive industries, e.g. mining, the mine itself exists as the material of labour, but not as raw material passing over into product, which latter must, in the manufacturing industry, by contrast, have a particular existence in all forms. In agriculture, seed, fertilizer, cattle etc., may be regarded as raw material as well as *matières instrumentales.* Agriculture forms a mode of production *sui generis,* because the organic process is involved, in addition to the mechanical and chemical process, and the natural reproduction process is merely controlled and guided; extractive industry (mining the most important) is likewise an industry *sui generis,* because no reproduction process whatever takes place in it, at least not one under our control or known to us. (Fishery, hunting etc. can involve a reproduction process; likewise forestry; this is therefore not necessarily purely extractive industry.) Now, in so far as the means of production, fixed capital as the product of capital and hence containing objectified surplus time, is itself constituted in such a way that it can be ejected by its producer as circulating capital, e.g. like machinery by the machine builder, before it becomes fixed capital, i.e. first enters into circulation as use value, [to that extent] its circulation contains no new aspect whatever. But in so far as it can never be sold while it serves at the same time as instrument of production, as e.g. railways, or in proportion as it is used up as such, it shares with fixed capital generally the quality that its value returns only successively; but there is also the addition that this return of its value includes the return of its surplus value, of the surplus labour objectified in it. It then has a special form of return.

The important thing now is that the production of capital thus appears as the production in definite portions of circulating capital and fixed capital, so that capital itself produces its double way of circulating as fixed capital and circulating capital.

Fixed capital and circulating capital. **Economist. Smith.** ***Counter-value of circulating capital must be produced within the year. Not so for fixed capital. It engages the production of subsequent years***

Before we settle the last point, first a few secondary matters. ‘Floating capital is consumed, fixed capital merely used, in the great work of production.’ (*Economist,* VI, p. 1.) The distinction between *consume* and *use* dissolves into gradual or rapid destruction. We need dwell on this point no further.

'Floating capital assumes an *infinite variety of forms,* fixed capital *has only one.'* (*Economist,* VI, p. 1.) [10] This 'infinite variety of forms', as regards the production process of capital itself, is much more correctly reduced by Adam Smith to a mere change of form. Fixed capital is of use to its master 'so long as it continues to remain in the same form'. That means it remains within the production process as use value, in a specific material presence. Circulating capital, by contrast (A. Smith, tome II, p. 197, 198) 'constantly passes out of his hands in a specific form' (as product) 'to return in another' (as condition of production) 'and brings profit only by means of this circulation and successive changes'. Smith does not speak here of the 'infinite variety of forms' in which circulating capital appears. Regarded materially, 'fixed capital' also assumes 'an infinite variety of forms'; but this proceeds from the metamorphoses which circulating capital passes through as itself a use value, and the 'infinite variety of forms' reduces itself, therefore, to the qualitative differences of the various phases of circulation. Regarded within a specific production process, circulating capital always returns in the same form of raw materials and money for wages., The material presence is the same at the end of the process as at the beginning. Incidentally, elsewhere the *Economist* itself reduces the 'infinite variety of forms' to the conceptually determined change of forms in circulation. 'The commodity is wholly consumed in the shape in which it is produced' (i.e. enters into circulation as use value and is ejected from it) 'and replaced in his hands in a *new shape'* (as raw material and wages), 'ready to repeat a *similar* operation' (rather, the same operation). (loc. cit. VI, p. 1.) [11] Smith also says explicitly that fixed capital 'requires no circulation'. (tome II, 197, 198.) With *fixed capital,* the value is imprisoned within a specific use value; with circulating capital, value takes the form of various different use values, likewise assumes as well as rejects the independent form distinct from every particular use value (as money); hence constant change of matter and form goes on.

'Circulating capital supplies him' (the entrepreneur) 'with the materials and wages of the workers, and sets industry into activity.' (A. Smith, tome II, p. 226.) *'Every fixed capital comes originally from a circulating capital,* and needs to be continually maintained *by means of a circulating capital.'* (loc. cit. p. 207.) 'Since so great a part of the circulating capital is being withdrawn continuously to be spent in the other two branches of the general social fund, this capital needs in turn to be renewed by continual replenishment, otherwise it would soon be reduced to nothing. These replenishments are drawn from three principal sources: the produce of the soil, of mines, and of fisheries.' (loc. cit. p. 208.)

<We have already developed one distinction emphasized by the *Economist:* 'Every production the whole cost of which is returned to the producer out of the *current income* of the country *is floating capital;* but every production, in respect of which only *an annual sum is paid for the use, is – fixed capital.'* (Notebook VI, p. 1.) [12] 'In the first case, the producer is entirely dependent on the country's current income.' (loc. cit.) We have seen that only part of the fixed capital returns in the time determined by circulating capital, which serves as the unit of its turnovers because it is the natural unit for the reproduction of the greatest part of food products and raw materials, just as, and because, it appears as the natural epoch in the life process (cosmic process) of the earth. This unit is the year, whose bourgeois calculation deviates more or less, but insignificantly, from its natural magnitude. The more the material presence of fixed capital corresponds to its concept, the more adequate its material mode of existence is, the more does its turnover time span a cycle of years. Since circulating capital is wholly exchanged first for money, secondly for its elements, it presupposes that a *countervalue has been produced* equal to its whole value (including the surplus value). It cannot be said that it enters or can enter into consumption entirely; since it must also in part serve in turn as raw material, or as an element for fixed capital; in short itself, in turn, as an element of production – a counter-production. A part of the use value ejected by capital as the product, as the result of the production process, becomes an object of consumption and thus drops out of the circulation of capital altogether; another part enters into another capital as a condition of production. This is itself posited in the circulation of capital *as such,* since it ejects itself from itself in the first half of circulation, as commodity, i.e. as use value; i.e. dismisses itself *with respect to itself* in this form from its own circulation as use value, article of consumption; but exchanges itself as money for commodity as condition of production, in the second half of its circulation. Thus, as circulating use value itself, it posits its material presence both as an article of consumption and as a

new element of production, or rather an element of reproduction. But in both cases the whole of its countervalue must be on hand; i.e. it must have been wholly produced during the year. For example, the sum of manufactured products which can be exchanged during a year for agricultural products is determined by the mass of the raw products produced in a year, counted from harvest to harvest. Since we speak here of capital *as such,* capital in the process of becoming, we are not yet concerned with anything else in addition – in that the many capitals are not yet present for us – nothing but it itself and simple circulation, out of which it absorbs value in the double form of money and commodity and into which it throws it in the double form of money and commodity. When an industrial people producing on the foundation of capital, such as the English, e.g., exchange with the Chinese, and absorb value in the form of money and commodity from out of their production process, or rather absorb value by drawing the latter within the sphere of the circulation of their capital, then one sees right away that the Chinese do not therefore need to produce as capitalists. Within a single society, such as the English, the mode of production of capital develops in one branch of industry, while in another, e.g. agriculture, modes of production predominate which more or less antedate capital. Nevertheless, it is (1) its necessary tendency to conquer the mode of production in all respects, to bring them under the rule of capital. Within a given national society this already necessarily arises from the transformation, by this means, of all labour into wage labour; (2) as to external markets, capital imposes this propagation of its mode of production through international competition. Competition is the mode generally in which capital secures the victory of its mode of production. Still, this much is clear: quite regardless of whether it is another capital or whether it is capital itself as another which stands on both sides of the successive exchanges, each time in the opposite aspect, both aspects are already posited before we proceed to examine this double movement from the circulation of capital *as such* itself. In the first phase it ejects itself out of the movement of capital as use value, as commodity, and exchanges itself for money. The commodity expelled from the circulation of capital is no longer the commodity as a moment of self-perpetuating value, as the presence of value. It is, thus, its presence as use value, its being for consumption. Capital is transposed out of the form of commodity into the form of money only because an exchanger appears *opposite it* in ordinary circulation as consumer, who transposes M into C; [completes] this transposition in its material aspect, so that he relates to the use value as use value, as consumer, and only in this way is the use value replaced for capital as *value.* Thus, capital creates articles of consumption, but ejects them from itself in this form, ejects them from its circulation. On the basis of the aspect developed so far, no other relations exist. The commodity which is ejected as such from the circulation of capital loses its character as value and fulfills the role of use value for consumption, as distinct from fulfilling it for production. But in the second phase of circulation, capital exchanges money for commodity, and its transformation into commodity now itself appears as a moment of value-positing, because the commodity is accepted as such into the circulation process of capital. While it presupposes consumption in the first phase, in the second it presupposes production, production for production; for value in the form of the commodity is here taken into the circulation of capital from the outside, or, the inverse process is undertaken in the first phase. The commodity, as use value for capital itself, can only be the commodity as an element, use value, for its production process. In its double form, the process presents itself in this way: capital *a* exchanges its product as C for capital *b*'s M in the first phase; in the second, capital *b* as C exchanges for capital *a*'s M. Or, in the first phase, capital *b* as M exchanges for capital *a*'s C, in the second, *a* as M for capital *b*'s C. That is, capital is simultaneously posited in each of the two circulation phases as M and C; but in two different capitals, which are always in the opposite phase of their circulation process. In the simple circulation process, the acts of exchange, C–M or M–C appear either as directly coinciding or as directly divided. Circulation is not only the succession of both forms of exchange, but it is at the same time each of them distributed to two different sides. But we are not yet concerned here with exchange among many capitals. This belongs to the theory of competition or to that of the circulation of capitals (of credit). What concerns us here is the presupposition of consumption on one side – of the commodity ejected from the movement of value as use value – and the presupposition of production for production – of value, posited as use value, as a condition of its reproduction posited externally to the circulation of capital on the other side – so that these two sides arise out of the examination of the simple form of the circulation of capital. This much is clear: Since the entire circulating capital exchanges as C for M in the first phase, and as M for C in the second, then, if we regard the year as the unit of time of its evolutions, its transformations are limited both by the annual reproduction of raw materials etc. (the commodity for which it exchanges as money must have been produced, a simultaneous production must correspond to it), and by the constant creation of an annual revenue (the part of M which exchanges for commodity as use value) to consume the product of capital which is ejected as use value. Since further-developed relations are not present yet, such revenues are only those of the capitalists themselves and those of the workers. The examination of the exchange of capital and revenue, by the way, another form of the relation of production and consumption, does not belong here yet. In another respect, since fixed capital is exchanged only to the extent it enters as value into circulating capital, since it is, thus, realized only in part during the year, it presupposes only a *partial counter-value,* i.e. only the partial production of this counter-value during the course of the year. It is paid for only in proportion to its wear. This much clear, then, which already follows from the difference introduced by fixed capital into the industrial cycle, namely that *it engages the production of subsequent years,* and, just as it contributes to the creation of a large revenue, it anticipates further labour as a counter-value. The anticipation of future fruits of labour is therefore in no way a consequence of the state debt etc., in short, not an invention of the credit system. It has *its roots in the specific mode of realization, mode of turnover, mode of reproduction of fixed capital.>*

Since we are essentially concerned here with grasping the pure, specific economic forms, hence with not joining together things that do not belong, it has thus become clear from the above that the different forms in which circulating capital and fixed capital bring revenue – as well as the examination of revenue generally – do not yet belong here at all; but only the different ways in which they return and affect the total turnover of capital, the movement of its reproduction generally. Nevertheless, the incidental points made here are important – in that they reject the economists' motley compilations, which have no place yet in the examination of the simple distinction between fixed capital and circulating capital – and because they showed us that the differences in revenue etc. have their basis in the difference of form between the reproduction of fixed and circulating capital. The issue here is still only the simple return of the value. Only later will it be found how the latter becomes the return of revenue, and that in turn becomes the difference in the determination of revenue.

Maintenance costs

We have said nothing so far about the *maintenance costs,* the *frais d'entretien* of fixed capital. These are partly the *matières instrumentales* it consumes in its action. They make up fixed capital in the first sense, as we have regarded it within the production process. These are circulating capital and may just as well serve for consumption. They become fixed capital only in so far as they are consumed in the production process, but do not have, like fixed capital proper, a material substance determined purely by their formal presence. The second part of these maintenance costs consists of the labour necessary for repairs.

Revenue of fixed capital and circulating capital

A. Smith's determination that every fixed capital comes originally from a circulating capital and must be constantly maintained by a circulating capital: 'Every fixed capital originally comes from a circulating capital and must be continually kept up at the latter's expense. *No fixed capital can yield revenue except at the expense of a circulating capital.'* (Storch, 26a.) [13] As to Storch's remark about revenue – an aspect which does not belong here – it is clear: fixed capital returns as value only in proportion as it becomes extinguished as use value, as fixed capital, and enters into circulating capital as value. Hence it can return in the form of a circulating capital only in so far as its *value* is concerned. But it does not circulate at all as use value. Further, since it has a use value only for production, it can return for individual use, for consumption, also only in the form of circulating capital. Improvements of the soil can directly enter chemically into the reproduction process and in this way be directly transformed into use values. But then they are consumed in their form as fixed capital. *A capital can bring revenue at all only in the form in which it enters into and returns from circulation, because the production of revenue in direct use values, use values not mediated through circulation, contradicts the nature of capital. Hence, since fixed capital returns as value only in the form of circulating capital, it can bring revenue only in this form.* Revenue is nothing whatsoever other than the part of the surplus value destined for immediate consumption. Its returns thus depend on the mode of return of value itself. Hence the different forms in which fixed capital and circulating capital bring revenue. Likewise, since fixed capital as such never enters circulation as use value, hence is never thrown out of the realization process as use value, it never serves for immediate consumption.

Now as to Smith, his view becomes clearer for us when he says that circulating capital must be annually replaced and constantly renewed by constantly drawing it from the sea, the soil, and from mines. Here, then, circulating capital becomes purely material for him; it is fished out by the hairs, chipped out, harvested; they are the movable primary products which are released from their connection with the earth, isolated, made movable thereby, or separated from their element in their ready-made individuality, like fish etc. Still regarded as pure material, it is further certain that, if Smith presupposes the production of capital and does not suppose himself at the beginning of the world, then every circulating capital likewise comes originally from a fixed capital. Without nets he can catch no fish; without a plough, till no fields; and without a hammer, etc., drive no mines. If he uses even so little as a stone for a hammer etc., then this stone is certainly no circulating capital, no capital of any sort, but rather a means of labour. As soon as he has to produce, man possesses the resolve to use a part of the available natural objects directly as means of labour, and, as Hegel correctly said it, subsumes them under his activity without further process of mediation. [14] The place where all capital, circulating as well as fixed, not only originally but continually comes from is the appropriation of alien labour. But this process presupposes, as we have seen, a continuous small-scale circulation, the exchange of wages for labour capacity, or *approvisionnement*. Assuming the production process of capital: *All capital* *returns only in the form of a circulating capital;* hence fixed capital can be renewed only by a process in which a part of circulating capital becomes fixed; hence, by the employment of part of the raw materials produced, and a part of labour consumed (hence also a part of the *approvisionnement* exchanged for living labour) for the production of fixed capital. In agriculture, e.g., part of the product is consumed by labour to build irrigation systems or a part of the grain is exchanged for guano, chemical substances etc., which are incorporated into the earth, but also in fact have no use value except in so far as they are surrendered to the chemical process of the soil. A part of the circulating capital has a use value only for the reproduction of the fixed capital, and is produced (even if its production consisted only of the labour time spent in changing its location) only for fixed capital. But fixed capital itself can be renewed as capital only by becoming a value-component of circulating capital, and its *elements are thus reproduced through the transformation of circulating capital* into fixed capital. *Fixed capital is as much a presupposition for the production of circulating capital as circulating capital is for the production of fixed capital.* Or, the reproduction of fixed capital requires: (1) the return of its value in the form of a circulating capital, for only in this way can it in turn be exchanged for the conditions of its production; (2) that a part of living labour and of the raw material be used to produce instruments of production, direct or indirect ones, instead of producing exchangeable products. Circulating capital enters as use value into fixed capital, just as does labour, while fixed capital enters as value into circulating capital; and, as movement (where it is direct machinery), as static motion, as form, into the use value.

Free labour = latent pauperism. Eden [15]

<In connection with our statements developed above, that pauperism latent in free labour, the following statements by Sir Fr. Morton Eden, Bt: *The State of the Poor, or an History of the Labouring Classes in England from the Conquest etc., 3* vols., 4º, London, 1797. (The quotations from Vol. I, bk I.) (In book I, chapter I, it says: ‘Our zone requires labour for the satisfaction of needs, and *therefore* at least *one part* of society must *always tirelessly* labour;

others labour in the arts etc., and some, who do not work, still have the products of diligence at their disposal. For this, these proprietors have only *civilization and order* to thank; they are purely the creatures of *civilized institutions.* For these have recognized that one can also obtain the fruits of labour through ways other than labour; the men of independent fortune owe their *wealth almost entirely to the labour of others,* not to their own ability, which is not at all better. What divides the rich from the poorer is not the ownership of land or of money, but rather the command of labour.' *Poverty* as such begins with the tiller's freedom – the feudal fetters to the soil, or at least the locality, had until then spared the legislature the task of occupying itself with the vagrants, poor etc. Eden believes that the various commercial guilds etc. also fed their own poor. He said: 'Without the most distant idea, then, of disparaging the numberless benefits derived for the country from manufactures and commerce, the result of this investigation seems to lead *to this inevitable conclusion that manufactures and commerce'* (i.e. the first sphere of production in which capital became predominant) 'are *the true parents of our national poor.'* In the same place: Beginning with Henry VII (where at the same time there began the clearing of the land of superfluous mouths through transformation of the tilled fields into pasture, continuing for more than 150 years, at least the litigation and legislative interference; hence the number of hands made available for industry grew), wages in industry were no longer fixed, only in agriculture. 11, Henry VII. (With free labour, wage labour is not yet completely posited. The labourers still have support in the feudal relations; their supply is still too small; capital hence still unable to reduce them to the minimum. Hence statutory determination of wages. So long as wages are still regulated by statute, it cannot yet be said either that capital has subsumed production under itself as capital, or that wage labour has attained the mode of existence adequate to it.) The act cited also mentions linen weavers, building craftsmen, shipwrights. The same act also fixes the hours of labour: 'Because many day labourers waste half the day, arrive late, leave early, take a long afternoon nap, spend a long time at breakfast, lunch and dinner, etc. etc.,' it ordains the following hours: 'from 15 March to 15 September, from 5 a.m., 1/2 hour breakfast, 1 1/2 dinner and siesta, 1/2 hour for noon meal, and work until between 7 and 8 p.m. In winter, however, no siesta during daylight; this permitted only from 15 May to 15 August.'>

<Wages again regulated in 1514, almost like the previous time. Hours of work again fixed. Whoever will not work upon application, arrested. Hence still *compulsory labour* by free workers at the given wages. They must first be *forced* to work within the conditions posited by capital. The propertyless are more inclined to become vagabonds and robbers and beggars than workers. The last becomes normal only in the developed mode of capital's production. In the prehistory of capital, state coercion to transform the propertyless into *workers* at conditions advantageous for capital, which are not yet here forced upon the workers by competition among one another.> (Very bloody means of coercion of this sort employed under Henry VIII et. al.) (Suppression of the *monasteries* under Henry VIII likewise frees many hands.) (Under Edward VI still sharper laws against able-bodied labourers who do not want to work. '1 Edw. VI, 3: Who is able to work, refuses to labour, and lives idle for 3 days, shall be branded with redhot iron on the breast with the letter V – and shall be adjudged the slave for two years of the person who should inform against such idler etc.' 'If he runs away from his master for 14 days he shall become his slave for life and be branded on forehead or cheek with letter S, and if he runs away a second time and shall be convicted thereof by two sufficient witnesses, he shall be taken as a felon and suffer pains of death.' (1376 first mention of the vagrants, sturdy rogues, 1388 the paupers.) (Similar cruel statute 1572 under Elizabeth.) [16]

The smaller the value of fixed capital in relation to its product, the more useful. – Movable, immovable, fixed and circulating. – Connection of circulation and reproduction. Necessity of reproducing use value in* definite *time

Circulating capital and fixed capital, which appeared earlier as changing forms of the same capital in the different phases of its turnover, are now, when fixed capital is developed to its highest form, posited at the same time as two different modes of the existence of capital. They become such through the difference in kind of their return. Circulating capital which returns slowly has a quality in common with fixed capital. But it distinguishes itself from it because its use value itself – its material presence – enters into circulation and is at the same time shed by it, thrown beyond the bounds of the turnover process; while fixed capital – to the extent that it has been developed at this point – enters into circulation only as value, and, as long as it is still in circulation as a use value, such as e.g. the machine in circulation, it is fixed capital only δυνάμει. However, this distinction between fixed capital and circulating capital, resting initially on the relation of the material presence of the capital, or of its presence as use value, towards circulation, must, with reproduction, be posited at the same time as the reproduction of the capital in the double form of fixed capital and circulating capital. In so far as the reproduction of capital in every form is the positing not only of objectified labour time, but rather of surplus labour time, not only reproduction of its value but of a surplus value, the production of fixed capital cannot therefore be different in this regard from the production of circulating capital. Hence, in the manufacture of instruments or machines – in all the forms where fixed capital appears first as circulating capital in its material presence, in its presence as use value before becoming fixed as fixed capital, i.e. before it is consumed, for it is precisely its consumption which binds it to the production phase and distinguishes it as fixed capital – there is no difference at all, as to the realization of capital, whether it reproduces itself in the form of fixed or of circulating capital. Hence no new economic determination enters here, either. But where fixed capital as such is thrown into circulation by its producer – and not as circulating capital – hence where *its proportionate use is sold, either for production* or for consumption – for in the transformation of C into M, which takes place in the first section of the circulation of capital, it is irrelevant to the latter whether the commodity in turn enters into the circulation sphere of another productive capital, or whether it serves the purpose of direct consumption; for the first capital, it is rather *always determined as a use value* whenever it ejects it from itself, exchanges it for M – there the mode of return must be different for the producer of fixed capital from that for the producer of circulating capital. The surplus value created by him can return only proportionately and successively with the value itself. This to be looked at in the next section. Finally, although circulating capital and fixed capital now appear as two different kinds, circulating capital is still posited through the consumption, the wear of fixed capital; while fixed capital, for its part, exists only as a circulating capital transformed into this specific form. All capital transformed into objectified productive power – all fixed capital – is a use value fixated in this form, and hence a use value snatched away from consumption as well as from circulation. The transformation of wood, iron, coal and living labour (hence also indirectly that of the products consumed by the worker) into the specific use values of a machine or a railway would not by itself turn them into fixed capital if the other determinants developed above were absent. When circulating capital is transformed into fixed capital, then a part of the use values in whose form capital circulated, as well as indirectly the part of the capital which exchanges for living labour, are transformed into capital whose counter-value is created only over a longer cycle; which enters into circulation as value only proportionately and successively; and which can be realized as value only through being used up in production. The transformation of circulating capital into fixed capital presupposes relative surplus capital, since it is capital employed not for direct production but rather for new means of production. Fixed capital itself can in turn serve as a direct instrument of production – as a means within the immediate production process. In this case its value enters into the product and is replaced by the successive return of the products. Or it does not enter into the immediate production process – appears rather as a general condition for production processes, such as buildings, railways etc., and its value can be replaced only through circulating capital, to whose creation it indirectly contributed. Questions of greater detail about the proportion in the production of fixed capital and circulating capital belong to the following section. If valuable machinery were employed to supply a small quantity of products, then it would not act as a force of production, but rather make the product infinitely more expensive than if the work had been done without machinery. It creates value not in so far as it has value – for the latter is simply replaced – but rather only in so far as it increases relative surplus time, or decreases necessary labour time. In the same proportion, then, as that in which its scope grows, the mass of products must increase, and the living labour employed relatively decrease. *The less the value of the fixed capital in relation to its effectiveness, the more does it correspond to its purpose.* All unnecessary fixed capital appears as *faux frais de production,* like all unnecessary circulation costs. If capital could possess the machinery without employing labour for the purpose, then it would raise the productive power of labour and diminish necessary labour without having to buy labour. The value of the fixed capital is therefore never an end in itself in the production of capital.

Circulating capital, then, is transformed into fixed capital, and fixed capital reproduces itself in circulating capital; both, only in so far as capital appropriates living labour.

‘Every saving in fixed capital is an increase in the net revenue of society.’ (A. Smith.) [17]

The final and last distinction cited by economists is that between *movable and immovable;* not in the sense that the former enters into the movement of circulation, the latter does not; rather in the sense that the former is physically fixed, immovable, in the same way as movable and immovable property is distinguished. For example, improvements sunk in the soil, aqueducts, buildings; and machinery itself in great part, since it must be physically fixed, to act; railways; in short, every form in which the product of industry is welded fast to the surface of the earth. This basically adds nothing to the determination of fixed capital; but it is indeed part of this character that it becomes fixed capital in a more eminent sense the more its use value, its material presence, corresponds to its specific economic form. The immovable use value, such as house, railway etc., is therefore the most tangible form of fixed capital. Of course, it can then still circulate in the same sense as immovable property generally – as title; but not as use value; it cannot circulate in the physical sense. Originally, the growth of movable property, its increase as against immovable, indicates the ascendant movement of capital as against landed property. But once the mode of production of capital is presupposed, the level to which it has conquered the conditions of production is indicated in the transformation of capital into immovable property. It thereby establishes its residence on the land itself, and the seemingly solid presuppositions given by nature, themselves [appear], in landed property, as merely posited by industry.

(Originally, life in the community and, through its mediation, the relationship to the earth as property, are basic presuppositions of the reproduction both of the individual and of the community. Among pastoral peoples, land and soil appear merely as precondition of the migratory life, hence appropriation does not take place. Fixed settlements with soil cultivation follow – thus landed property is initially held in common, and even where it advances to private property the individuals' connection to it appears as posited by his relation to the community. It appears as a mere fief of the community; etc. etc. The transformation of the latter into mere exchangeable value – its mobilization – is the product of capital and of the complete subordination of the state organism to it. Land and soil, even where they have become private property, are therefore exchange value only in a restricted sense. Exchange value begins in the isolated natural product, separated from the earth and individualized through industry (or mere appropriation). Individual labour first arises here too. Exchange as such does not begin within the original communes, but on their boundaries, where they cease to be. Of course, to exchange the land, their residence, to pawn it to alien communes, would be treason. Exchange can expand only little by little from its original realm, movable property, to immovable property. Only through expansion of the former does it little by little gain control over the latter. Money is the chief agent in this process.)

A. Smith at first distinguishes circulating capital and fixed capital by their role in the *production process.* Only later does he adopt the expression: 'One can gainfully lay out a capital in different ways, (1) as circulating capital, (2) as fixed capital.' [18] This second expression obviously does not belong to the examination of this distinction as such, since fixed capital and circulating capital first have to be presupposed as two kinds of capital before we can speak about how to lay out capital gainfully in both forms.

'The total capital of each entrepreneur is necessarily divided into his fixed capital and his circulating capital. If the sum is equal, then the one becomes larger as the other diminishes.' (A. Smith, tome II, p. 226.)

Since capitals are (1) divided into fixed and circulating capital in unequal portions; (2) [have] an interrupted or uninterrupted production phase and return from more distant or nearer markets, hence, unequal circulation time; it follows that the determination of the surplus value created in a given time, e.g. annually, must be unequal because the number of reproduction processes in the given period is unequal. The amount of value created appears determined not simply by the labour employed during the immediate production process, but by the degree to which this exploitation of labour can be repeated within a given period of time.

Finally, then: While, in the examination of the simple production process, capital appeared to realize itself as value only in connection with wage labour, and circulation lay alongside, without connection to it, here, in its reproduction process, circulation is included in it in both the moments of circulation, C–M–M–C (as a system of exchanges through which it must pass, and to which the same number of qualitative changes within it correspond). In so far as its form as money is the point of departure and hence of return, circulation appears included in it as M–C–C–M. It contains both circular courses, and not merely as either change of form or change of substance, but rather as both of them included within the determination of value itself. The production process, as containing within itself the conditions of its renewal, is a reproduction process whose speed is determined by various relations developed above, which all arise from differences of circulation. The reproduction of capital also contains the reproduction of the use values in which it is realized – or the constant renewal and reproduction by human labour of the use values which enter human consumption and are themselves perishable. The change of substance and of form subordinated to human need through human labour appears from the viewpoint of capital as its own reproduction. It is at bottom the constant reproduction of labour itself. 'Capital values perpetuate themselves by reproduction: the products which compose a capital are consumed just like any others; but their value, at the same time as it is destroyed by consumption, is reproduced in other materials or in the same one.' (Say, 14.) [19] Exchange and a system of exchanges, and, included in that, the transformation into money as independent value, appears as condition and barrier for the reproduction of capital. With capital, production itself is on all sides subordinate to exchange. These exchange operations, circulation as such, produce no surplus value, but are conditions for its realization. They are conditions of the *production of capital itself,* in so far as its *form as capital* is posited only to the extent that it passes through them. The reproduction of capital is at the same time the production of specific formal conditions; of specific modes of relationship in which personified objectified labour is posited. Circulation is thus not merely the exchange of the product for the conditions of production – i.e. of produced wheat, e.g., for seed, new labour etc. The worker must exchange his product for the conditions of production, so as to begin anew, in every form of production. The peasant producing for immediate consumption also transforms part of the product into seed, instrument of labour, beasts of burden, fertilizer etc., and begins his labour anew. The transformation into money is necessary for the reproduction of capital as such, and its reproduction is necessarily the production of surplus value. * Although labour must merely maintain the value of what we earlier called constant capital in one production process, it must constantly reproduce it in another, since what appears as presupposition of material and instrument in one production process is product in the other, and this renewal, reproduction, must constantly proceed simultaneously.

* In regard to the reproduction phase (especially circulation time), note that use value itself places limits upon it. Wheat must be reproduced in a year. Perishable things like milk etc. must be reproduced more often. Meat on the hoof does not need to be reproduced quite so often, since the animal is alive and hence resists time; but slaughtered meat on the market has to be reproduced in the form of money in the very short term, or it rots. The reproduction of value and of use value partly coincide, partly not.

Capital as Fructiferous. Transformation of Surplus Value into Profit

We now come to the

THIRD SECTION. CAPITAL AS FRUCTIFEROUS. INTEREST. PROFIT. (PRODUCTION COSTS ETC.)

Rate of profit. – Fall of the rate of profit. – Rate of profit. – Sum of profit. – Atkinson. A. Smith. Ramsay. Ricardo. – Surplus value as profit *always expresses a lesser proportion. – Wakefield. Carey. Bastiat*

Capital is now posited as the unity of production and circulation; and the surplus value it creates in a given period of time, e.g. in one year, is $= ST/(p + c) = ST/R$ or $= S(T/p - T/p \times c/(c + p))$. Capital is now realized not only as value which reproduces itself and is hence perennial, but also as value which posits value. Through the absorption of living labour time and through the movement of its own circulation (in which the movement of exchange is posited as its own, as the inherent process of objectified labour), it relates to itself as positing new value, as producer of value. It relates as the foundation to surplus value as that which it founded. Its movement consists of relating to itself, while it produces itself, at the same time as the foundation of what it has founded, as value presupposed to itself as surplus value, or to the surplus value as posited by it. In a definite period of time which is posited as the unit measure of its turnovers because it is the natural measure of its reproduction in agriculture, capital produces a definite surplus value, which is determined not only by the surplus value it posits in one production process, but rather by the number of repetitions of the production process, or of its reproductions in a specified period of time. Because of the inclusion of circulation, of its movement outside the immediate production process, within the reproduction process, surplus value *appears* no longer to be posited by its simple, direct relation to living labour; this relation appears, rather, as merely a moment of its total movement. Proceeding from itself as the active subject, the subject of the process – and, in the turnover, the direct production process indeed appears determined by its movement as capital, independent of its relation to labour – capital relates to itself as self-increasing value; i.e. it relates to surplus value as something posited and founded by it; it relates as well-spring of production, to itself as product; it relates as producing value to itself as produced value. It therefore no longer measures the newly produced value by its real measure, the relation of surplus labour to necessary labour, but rather by itself as its presupposition. A capital of a certain value produces in a certain period of time a certain surplus value. Surplus value thus measured by the value of the presupposed capital, capital thus posited as self-realizing value – is *profit;* regarded not *sub specie aeternitatis,* but *sub specie – capitalis,* the surplus value is profit; and capital as capital, the producing and reproducing value, distinguishes itself within itself from itself as profit, the newly produced value. The product of capital is *profit.* The magnitude, surplus value, is therefore measured by the value-magnitude of the capital, and the *rate of profit* is therefore determined by the proportion between its value and the value of capital. A very large part of what belongs here has been developed above. [20] But the anticipated material is to be put here. In so far as the newly posited value, which is of the same nature as the capital, is itself in turn taken up into the production process, itself in turn maintains itself as capital, to that extent the capital itself has grown, and now acts as a capital of greater value. After it has distinguished the profit, as newly reproduced value, from itself as presupposed, self-realizing value, and has posited profit as the measure of its realization, it suspends the separation again, and posits it in its identity to itself as capital which, grown by the amount of the profit, now begins the same process anew in larger dimensions. By describing its circle it expands itself as the subject of the circle and thus describes a self-expanding circle, a spiral.

The general laws developed previously here briefly summarized thus: The real surplus value is determined by the relation of surplus labour to necessary labour, or by the portion of the capital, the portion of objectified labour, which exchanges for living labour, relative to the portion of objectified labour by which it is replaced. But surplus value in the form of profit is measured by the total value of the capital presupposed to the production process. Presupposing the same surplus value, *the same surplus labour in proportion to necessary* *labour,* then, the *rate of profit* depends on the relation between the part of capital exchanged for living labour and the part existing in the form of raw material and means of production. Hence, the smaller the portion exchanged for living labour becomes, the smaller becomes the rate of profit. Thus, in the same proportion as capital takes up a larger place as capital in the production process relative to immediate labour, i.e. the more the relative surplus value grows – the value-creating power of capital – the more *does the rate of profit fall.* We have seen that the magnitude of the capital already presupposed, presupposed to reproduction, is specifically expressed in the growth of fixed capital, as the produced productive force, objectified labour endowed with apparent life. The total value of the producing capital will express itself in each of its portions as a diminished proportion of the capital exchanged for living labour relative to the part of capital existing as constant value. Take e.g. manufacturing industry. In the same proportion as fixed capital grows here, machinery etc., the part of capital existing in raw materials must grow, while the part exchanged for living labour decreases. Hence, the rate of profit falls relative to the total value of the capital presupposed to production – and of the part of capital acting as capital in production. The wider the existence already achieved by capital, the narrower the relation of newly created value to presupposed value (reproduced value). *Presupposing equal surplus value, i.e. equal relation of surplus labour and necessary labour,* there can therefore be an unequal profit, and it must be unequal relative to the size of the capitals. The rate of profit can rise although real surplus value falls. Indeed, the capital can grow and the rate of profit can grow in the same relation if the relation of the part of capital presupposed as value and existing in the form of raw materials and fixed capital rises at an equal rate relative to the part of the capital exchanged for living labour. But this equality of rates presupposes growth of the capital without growth and development of the productive power of labour. One presupposition suspends the other. This contradicts the law of the development of capital, and especially of the development of fixed capital. Such a progression can take place only at stages where the mode of production of capital is not yet adequate to it, or in spheres of production where it has assumed predominance only formally, e.g. in agriculture. Here, natural fertility of the soil can act like an increase of fixed capital – i.e. relative surplus labour can grow – without the amount of necessary labour diminishing. (E.g. in the *United States.)* The *gross profit,* i.e. the surplus value, regarded apart from its formal relation, not as a proportion but rather as a simple magnitude of value without connection with any other, will grow on the average *not as does the rate of profit, but as does the size of the capital.* Thus, while the rate of profit will be inversely related to the value of the capital, the *sum of profit* will be directly related to it. However, even this statement is true only for a restricted stage of the development of the productive power of capital or of labour. A capital of 100 with a profit of 10% yields a smaller sum of profit than a capital of 1,000 with a profit of 2%. In the first case the sum is 10, in the second 20, i.e. the gross profit of the larger capital is twice as large as that of the 10 times smaller capital, although the rate of the smaller capital's profit is 5 times greater than that of the larger. But if the larger capital's profit were only 1%, then the sum of its profit would be 10, like that for the 10 times smaller capital, because the rate of profit would have declined in the same relation as its size. If the rate of profit of the capital of 1,000 were only 1/2%, then the sum of its profit would be only half as large as that of the smaller capital, only 5, because the rate of profit would be 20 times smaller. Thus, expressed in general terms: if the rate of profit declines for the larger capital, but not in relation with its size, then the gross profit rises although the rate of profit declines. If the profit rate declines relative to its size, then the gross profit remains the same as that of the smaller capital; remains stationary. If the profit rate declines more than its size increases, then the gross profit of the larger capital decreases relative to the smaller one in proportion as its rate of profit declines. This is in every respect the most important law of modern political economy, and the most essential for understanding the most difficult relations. It is the most important law from the historical standpoint. It is a law which, despite its simplicity, has never before been grasped and, even less, consciously articulated. Since this decline in the rate of profit is identical in meaning (1) with the productive power already produced, and the foundation formed by it for new production; this simultaneously presupposing an enormous development of scientific powers; (2) with the decline of the part of the capital already produced which must be exchanged for immediate labour, i.e. with the decline in the immediate labour required for the reproduction of an immense value, expressing itself in a great mass of products, great mass of products with low prices, because the total sum of prices is = to the reproduced capital + profit; (3) [with] the dimension of capital generally, including the portion of it which is not fixed capital; hence intercourse on a magnificent scale, immense sum of exchange operations, large size of the market and all-sidedness of simultaneous labour; means of communication etc., presence of the necessary consumption fund to undertake this gigantic process (workers' food, housing etc.); hence it is evident that the material productive power already present, already worked out, existing in the form of fixed capital, together with the population etc., in short all conditions of wealth, that the greatest conditions for the reproduction of wealth, i.e. the abundant development of the social individual – that the development of the productive forces brought about by the historical development of capital itself, when it reaches a certain point, suspends the self-realization of capital, instead of positing it. Beyond a certain point, the development of the powers of production becomes a barrier for capital; hence the capital relation a barrier for the development of the productive powers of labour. When it has reached this point, capital, i.e. wage labour, enters into the same relation towards the development of social wealth and of the forces of production as the guild system, serfdom, slavery, and is necessarily stripped off as a fetter. The last form of servitude assumed by human activity, that of wage labour on one side, capital on the other, is thereby cast off like a skin, and this casting-off itself is the result of the mode of production corresponding to capital; the material and mental conditions of the negation of wage labour and of capital, themselves already the negation of earlier forms of unfree social production, are themselves results of its production process. The growing incompatibility between the productive development of society and its hitherto existing relations of production expresses itself in bitter contradictions, crises, spasms. The violent destruction of capital not by relations external to it, but rather as a condition of its self-preservation, is the most striking form in which advice is given it to be gone and to give room to a higher state of social production. It is not only the growth of scientific power, but the measure in which it is already posited as fixed capital, the scope and width in which it is realized and has conquered the totality of production. It is, likewise, the development of the population etc., in short, of all moments of production; in that the productive power of labour, like the application of machinery, is related to the population; whose growth in and for itself already the presupposition as well as the result of the growth of the use values to be reproduced and hence also to be consumed. Since this decline of profit signifies the same as the decrease of immediate labour relative to the size of the objectified labour which it reproduces and newly posits, capital will attempt every means of checking the smallness of the relation of living labour to the size of the capital generally, hence also of the surplus value, if expressed as profit, relative to the presupposed capital, by reducing the allotment made to necessary labour and by still more expanding the quantity of surplus labour with regard to the whole labour employed. Hence the highest development of productive power together with the greatest expansion of existing wealth will coincide with depreciation of capital, degradation of the labourer, and a most straitened exhaustion of his vital powers. These contradictions lead to explosions, cataclysms, crises, in which by momentaneous suspension of labour and annihilation of a great portion of capital the latter is violently reduced to the point where it can go on. These contradictions, of course, lead to explosions, crises, in which momentary suspension of all labour and annihilation of a great part of the capital violently lead it back to the point where it is enabled [to go on] fully employing its productive powers without committing suicide. [21] Yet, these regularly recurring catastrophes lead to their repetition on a higher scale, and finally to its violent overthrow. There are moments in the developed movement of capital which delay this movement other than by crises; such as e.g. the constant devaluation of a part of the existing capital: the transformation of a great part of capital into fixed capital which does not serve as agency of direct production; unproductive waste of a great portion of capital etc. (Productively employed capital is always replaced doubly, as we have seen, in that the positing of value by a productive capital presupposes a counter-value. The unproductive consumption of capital replaces it on one side, annihilates it on the other. * That the fall of the rate of profit can further be delayed by the omission of existing deductions from profit, e.g. by a lowering of taxes, reduction of ground rent etc., is actually not our concern here, although of importance in practice, for these are themselves portions of the profit under another name, and are appropriated by persons other than the capitalists themselves. † The fall [in the rate of profit] likewise delayed by creation of new branches of production in which more direct labour in relation to capital is needed, or where the productive power of labour is not yet developed, i.e. the productive power of capital.) (Likewise, monopolies.) 'Profit is a term signifying the increase of capital or wealth; so failing to find the laws which govern the rate of profit, is failing to find the laws of the formation of capital.' (William Atkinson, *Principles of Political Economy etc.,* London, 1840, p. 55.) He has however failed to understand even what the rate of profit is. A. Smith explained the fall of the rate of profit, as capital grows, by the competition among capitals. [22] To which Ricardo replied that competition can indeed reduce profits in the various branches of business to an average level, can equalize the rate, but cannot depress this average rate itself. [23] A. Smith's phrase is correct to the extent that only in competition – the action of capital upon capital – are the inherent laws of capital, its tendencies, realized. But it is false in the sense in which he understands it, as if competition imposed laws on capital from the outside, laws not its own. Competition can permanently depress the rate of profit in all branches of industry, i.e. the average rate of profit, only if and in so far as a general and permanent fall of the rate of profit, having the force of a law, is conceivable *prior to* competition and regardless of competition. Competition executes the inner laws of capital; makes them into compulsory laws towards the individual capital, but it does not invent them. It realizes them. To try to explain them simply as results of competition therefore means to concede that one does not understand them. Ricardo, for his part, says: 'No accumulation of capitals can *permanently* reduce profits unless an equally permanent cause raises wages.' (p. 92, tome II, Paris 1835, translated by Constancio.) He finds this cause in the growing, relatively growing unproductivity of agriculture, 'the growing difficulty of increasing the quantity of subsistence', i.e. in the growth of proportionate wages, so that labour's real wage is no greater, but the product obtains more labour; in a word, a greater portion of necessary labour is required for the production of agricultural products. The falling rate of profit hence corresponds, with him, to the nominal growth of wages and real growth of ground rent. His one-sided mode of conceiving it, which seizes on only one single case, just as the rate of profit can fall because wages momentarily rise etc., and which elevates a historical relation holding for a period of 50 years and reversed in the following 50 years to the level of a general law, and rests generally on the historical disproportion between the developments of industry and agriculture – in and for itself it was strange that Ricardo, Malthus, etc. constructed general and eternal laws about physiological chemistry at a time where the latter hardly existed – this method that Ricardo has of conceiving the matter has therefore been attacked from all sides, partly because of an instinct that it is wrong and unsatisfactory; but mostly for its true rather than for its false aspects.

> * The same law expresses itself simply – but this expression to be looked at later in the theory of population – as the relation of the growth of population – namely its labouring part – to the capital already presupposed.

> † The other way in which this same law also expresses itself, in the relation among many capitals, i.e. in competition, likewise belongs in another section. It can also be formulated as a law of the accumulation of capitals; as e.g. by Fullarton. We shall come to this in the next section. It is important to call attention to the point that this law deals not simply with the development of productive power δυνάμει, but at the same time with the scope in which this productive power acts as capital, and is realized as fixed capital above all in one respect, and as population in the other.

‘A. Smith thought that accumulation or increase of stock in general lowered the rate of profits in general, on the same principle which makes the increase of stock in any particular trade lower the profits of that trade. But such increase of stock in a particular trade *means* an increase in a greater *proportion* than stock is at the same time increased in other trades. It is relative.’ (p. 9, *An Inquiry into those Principles respecting the Nature of Demand and the Necessity of Consumption, lately advocated by Mr Malthus.* London, 1821.) ‘The competition among the industrial capitalists can level profits which rise particularly above the level, but cannot lower this ordinary level.’ (Ramsay, IX, 88.) [24] (Ramsay and other economists correctly distinguish between whether productivity grows in the branches of industry which make fixed capital, and naturally wages, or in other industries, e.g. luxury-goods industries. The latter cannot diminish necessary labour time. This they can do only through exchange for agricultural products of other countries, which is then the same as if productivity had increased in agriculture. Hence the importance of free trade in grain for the industrial capitalists.) Ricardo says (English edition *On the Principles of Political Economy and Taxation.* 3rd edition, London, 1821): ‘The farmer and manufacturer can no more live without profits, than the labourer without wages.’ (p. 23 loc. cit.) ‘There is a natural tendency for profits to fall, because in the progress of society and of wealth, the additional food requires more and more labour. This tendency, this gravitation of profits, is delayed in repeated intervals by improvement of the machinery involved in the production of necessaries, as well as by discoveries in the science of agriculture, which reduce the costs of production.’ (loc. cit. p. 121.) Ricardo at once identifies profit directly with surplus value; he did not make this distinction at all. *But whereas the rate of surplus value is determined by the relation of surplus labour employed by the capital to necessary labour, the rate of profit is nothing but the relation of the surplus value to the total value of the capital presupposed to production.* Its proportion falls and rises, hence, in relation with the part of the capital exchanged for living labour relative to the part existing as material and fixed capital. *Under* ALL *circumstances, the surplus value regarded as profit must express a smaller proportion of the gain than the real proportion of the surplus value.* For, under all circumstances, it is measured by the total capital, which is always larger than that employed for wages and exchanged for living labour. Since Ricardo simply mixes surplus value and profit together in this way, and since the surplus value can constantly decline, can *tendentially* decline only if the relation of surplus labour to necessary labour, i.e. to the labour required for the reproduction of labouring capacity, declines, but since the latter is possible only if the productive force of labour declines, Ricardo assumes that the productive force of labour decreases in agriculture, although it grows in industry, with the accumulation of capital. He flees from economics to seek refuge in organic chemistry. We have demonstrated the necessity of this tendency without any reference to ground rent, nor did we have to refer e.g. to rising demand for labour etc. The connection between ground rent and profit is to be treated only in the examination of ground rent itself, does not belong here. But modern chemistry has demonstrated that Ricardo’s physiological postulate, expressed as a general law, is false. [25] As for Ricardo’s disciples, in so far as they are more than his pious echoes, they have quietly let drop whatever is unpleasant to them in their master's principles, as has the newer economics generally. To drop the problem is their general method of solving it. Other economists, such as e.g. Wakefield, seek refuge in the examination of the *field of employment* for the growing capital. This belongs in the examination of competition, and is rather the *difficulty for capital to realize the growing profit, hence denial of the inherent tendency towards the fall of the rate of profit.* But the need for capital to seek a constantly more extensive field of employment is itself again a consequence. One cannot count Wakefield and similar people among those who have posed the question itself. (Is in certain respects a reproduction of A. Smith's view.) Finally, the harmonists among the most modern economists, at their head the American, Carey, whose most obnoxious adherent was the Frenchman Bastiat (by the way, it is the nicest irony of history that the Continental free-traders worship Mr Bastiat, who, for his part, gets his wisdom from the protectionist, Carey), accept the fact of the tendency of the rate of profit to fall in measure as productive capital grows. But they explain it simply and entirely as due to growth in the value of labour's share; growth of the proportion of the total product obtained by the worker, while the capital is allegedly compensated for this by the growth of gross profits. The unpleasant contradictions, antagonisms within which classical economics moves, and which Ricardo emphasizes with scientific ruthlessness, are thus watered down into well-to-do harmonies. In Carey's development, it sometimes seems as if he still had a mind of his own. This concerns a law which we need look at only in the doctrine of competition, where we will then settle accounts with him. We can finish up here with the witlessness of Bastiat, who expresses commonplaces in a paradoxical way, grinds and polishes them into facets, and hides an utter poverty of ideas under a cover of formal logic. * In the *Gratuité du Crédit.* Discussion entre M. Fr. Bastiat et M. Proudhon, Paris, 1850 (Proudhon, by the way, cuts a highly ridiculous figure in this polemic, where he hides his dialectical feebleness under a great show of rhetoric), it says in Bastiat's letter No. VIII (where this noble spirit, by the way, simply transforms, with his conciliatory dialectic, the gain resulting from the simple division of labour both for the road-builder and for the road-user into a gain owed to the 'road' (i.e. to capital) itself): 'To the degree that capitals increase (and the products with them), the absolute part returning to capital increases, and its proportional part diminishes. To the degree that capitals increase (and the products with them), labour's proportional part and its absolute part increase ... Since capital's absolute part grows even while it successively obtains only 1/2, 1/3, 1/4, 1/5 of the total product, it follows that labour, which successively obtains 1/2, 2/3, 3/4, 4/5, evidently receives a progressively increasing share of the whole, both in the proportional and in the absolute sense.' He gives as *illustration*:

Total product		*Capital's share*	*Labour's share*
1st period	1,000	1/2 or 500	1/2 or 500
2nd	1,800	1/3 or 600	2/3 or 1,200
3rd	2,800	1/4 or 700	3/4 or 2,100
4th	4,000	1/5 or 800	4/5 or 3,200

(p. 130, 131.)

* Some things from Notebook III about the antithesis of Carey and Bastiat can be included at this point. [26]

The same joke is repeated (p. 288) in the form of increasing gross profit with declining rate of profit, but increasing mass of products sold at lower prices, and weighty words are spoken on that occasion about 'the law of unlimited decline which never reaches zero, a law well known to mathematicians'. (p. 288.) 'Here we have' (hawking his wares) 'an endlessly decreasing multiplier, because the multiplicand is ever growing.' (p. 288 loc. cit.)

Ricardo had anticipated his Bastiat. Emphasizing that the sum of profit grows as capital grows despite the decline of the rate of profit – thus anticipating Bastiat's whole profundity – he does not fail to note that this progression 'is true only for a certain time'. He says, word for word: 'Regardless of how the rate of profit on stock may decline in consequence of the accumulation of capital on the land and of a rise of wages' (by which Ricardo understands, N.B., the rise of the cost of production of the agricultural products necessary for the maintenance of labour capacity), 'the aggregate amount of profits must nevertheless grow. Supposing, then, that in repeated accumulations of £100,000 the rate of profits fell from 20 to 19, 18, 17%, we should expect that the whole amount of profits received by the successive owners of capital would be always progressive; that it would be greater with the capital of £200,000 than with that of 100,000; yet greater with 300,000; and so on, increasing, although at a decreasing rate, with every increase of capital. *However, this progress is true only for a certain time:* thus 19% on £200,000 is more than 20 on 100,000; 18% on 300,000 more than 19% on 200,000; but after capital has accumulated to a large amount and profits have fallen, further accumulation diminishes the sum of profits. Thus, supposing the accumulation of 1,000,000 and profits of 7%, then the total amount of profit will be £70,000; now if an addition of 100,000 is made to the million, and profits fall to 6%, then £66,000 or a decrease of £4,000 will be received by the owners of the stock, although the amount of capital will be increased from 1,000,000 to 1,100,000.' (loc. cit. p. 124, 125.) Of course this does not prevent Mr Bastiat from undertaking the operation of making a growing multiplicand grow in such a way that, with the declining multiplier, it produces a growing product, in true elementary-school pupil style, just as the laws of production did not prevent Dr Price from constructing his compound interest calculations. Because the rate of profit declines, it declines relative to wages, which must consequently grow proportionally and absolutely. So reasons Bastiat. (Ricardo observed this tendency towards the decline of the profit rate with the growth of capital; and since he confuses profit with surplus value, he was forced to make wages rise in order to let profits fall. But since he saw at the same time that wages really declined more than they rose, he let the value of wages grow, i.e. the quantity of necessary labour, without letting its use value grow. Thus in fact he only let ground rent increase. The harmonic Mr Bastiat discovers, however, that, with the accumulation of capitals, wages rise proportionally and absolutely.) He assumes what he has to prove, that the decline of the profit rate is identical with the increase in the rate of wages, and then 'illustrates' his presupposition with an arithmetical example which appears to have amused him greatly. If the decline of the profit rate expresses nothing more than the decline of the relation in which the total capital requires living labour for its reproduction, then it is another matter. Mr Bastiat overlooks the trifling circumstance that, in his presupposition, while the profit rate on capital declines, the capital itself increases, the capital presupposed to production. Now even Mr Bastiat ought to have had an inkling that the value of the capital cannot grow without appropriating surplus labour. The misery of agricultural overproduction, recorded in French history, could have shown him that the mere increase of products does not increase their value. The question would then revolve simply around an investigation of whether the fall of the profit rate is identical with the growth of the rate of surplus labour relative to necessary labour, or, instead, with the fall of the total rate of living labour employed relative to the reproduced capital. Mr Bastiat also therefore divides the product simply between capitalist and worker, instead of dividing it into raw material, instrument of production and labour, and asking himself in what proportional parts its value in exchange is applied against these different portions. The part of the product exchanged for raw material and instrument of production is obviously none of the workers' business. What they divide with capital, as wages and profit, is nothing other than the newly added living labour itself. But what particularly worries Bastiat is who, after all, is to eat up the increased product? Since the capitalist eats up a relatively small part, does not the worker have to eat up a relatively large one? Particularly in France, whose total production is sufficient only in Bastiat's fantasy to give anyone at all very much to eat, Mr Bastiat could have found convincing testimony that a mass of parasitic bodies come to cluster around capital, and, under one or another title, they lay hands on so much of the total production as to leave little danger of the workers being overwhelmed by abundance. It is clear, of course, that with large-scale production the total mass of labour employed can increase although the proportion of labour employed relative to capital decreases, and that there is no obstacle, therefore, which prevents an increasing working population from requiring a greater mass of products as capital increases. Incidentally, Bastiat – in whose harmonic brain all cows are grey – (see above, wages), [27] confuses the decline of interest with the increase of wages, since this is rather an increase of industrial profit, which concerns the workers not at all, but concerns only the relation in which different species of capitalists divide up the total profit among themselves.

Capital and revenue (profit). Production and distribution. Sismondi. – Production costs from capital's viewpoint. Profit,

ditto. – Inequality of profits. Equalization and communal rate of profit. – Transformation of surplus value into profit. – Laws

Back to our topic. The product of capital, then, is profit. By relating to itself as profit, it relates to itself as the *source of the production of value, and the rate of profit expresses the proportion to which it has increased its own value.* But the capitalist is not merely capital. He has to live, and since he does not live by working he must live from profit, i.e. from the alien labour he appropriates. Thus capital is posited as the source of wealth. Since capital has incorporated productivity into itself as its inherent quality, capital relates to profit as *revenue.* It can consume a part of it (seemingly all of it, but this will prove to be false) without ceasing to be capital. After consumption of this fruit it can bear new fruit. It can represent consumption wealth without ceasing to represent the general form of wealth, something which money in simple circulation could not possibly do. The latter had to *abstain in order to remain the general form* of wealth; or, if it exchanged for real wealth, for consumer gratifications, it ceased to be the general form of wealth. Thus profit appears as a *form of distribution,* like wages. But since capital can grow only through the retransformation of profit into capital – into surplus capital – profit is at the same time a *form of production for capital;* just exactly as wages are a mere *relation of production* from the standpoint of capital, a relation of distribution from the worker's standpoint. This shows that the relations of distribution are themselves produced by the relations of production, and represent the latter themselves from another point of view. It shows further that the relation of production to consumption is posited by production itself. Note the fatuousness of all bourgeois economists, including e.g. J. St. Mill, who considers the bourgeois relations of production as eternal, but their forms of distribution as historical, and thereby shows that he understands neither the one nor the other. As to simple exchange, Sismondi correctly remarks: 'An exchange always presupposes two values; each may have a different share; but the *quality of capital and revenue* does not follow from the object exchanged; it attaches to the person who is its owner.' (Sismondi, VI.) [29] Hence the simple exchange relation provides no basis for the explanation of revenue. The quality of a value obtained in exchange, whether it represents capital or revenue, is determined by relations lying outside simple exchange. Absurd, therefore, to want to reduce these more complex forms to the earlier, simpler exchange relations, as do the harmonic freetraders. From the standpoint of simple exchange, and considering accumulation as the mere accumulation of money (exchange value), capital's profit and revenue are impossible. 'If the rich spend the accumulated wealth for luxury products – and they can obtain commodities only through exchange – then their funds would soon be exhausted ... But, in the social order, wealth has achieved the quality of reproducing itself through *alien labour.* Wealth, like labour, and *through labour,* yields an annual fruit which may be *destroyed* each year without the rich man thereby becoming poorer. This fruit is the revenue springing from capital.' (Sismondi, IV.) [30] While profit thus appears in one respect as the result of capital, it appears in the other as the *presupposition of capital formation.* Thus is posited anew the circular movement in which the result appears as presupposition. 'Thus a part of the revenue became transformed into capital, into a permanent, self-multiplying value, which did not perish; this value tore itself free from the commodity which created it; like a metaphysical, insubstantial quality it always remained in possession of the same *cultivateur*' (capitalist), 'assuming various forms for him.' (Sismondi, VI) [31]

When capital is posited as profit-creating, as a source of wealth independently of labour, each part of the capital is thereby assumed to be equally productive. Just as surplus value in the form of profit is measured against the total value of the capital, so does it appear to be created by its different components to an equal degree. Thus its circulating part (the part consisting of raw materials and *approvisionnement)* brings no more profit than the component which consists of the fixed capital, and, more particularly, profit accrues to these component parts in proportion to their magnitude.

Since the profit of capital is realized only in the price which is paid for it, for the use value created by it, profit is determined by the *excess of the price obtained over the price which covers outlays.* Since, furthermore, this realization proceeds only through *exchange,* the individual capital's *profit is not necessarily restricted by its surplus value,* by the surplus labour contained in it; but is relative, rather, to the excess of price obtained in exchange. It can exchange more than its *equivalent, and then its profit is* *greater than its surplus value.* This can be the case only to the extent that the other party to the exchange does not obtain an equivalent. The total surplus value, as well as the *total profit,* which is only *surplus value itself, computed differently,* can neither grow nor decrease through this operation, ever; what is *modified thereby* is not it, but only *its distribution among the different capitals.* However, this examination belongs only with that of the many capitals, it does not yet belong here. In relation to profit, the value of the capital presupposed in production appears as *advances – production costs* which must be replaced in the product. After deduction of the part of the price which replaces them, the excess forms the profit. Since surplus labour – of which profit and interest are, both, only portions – costs capital nothing, hence does not figure as part of the value advanced by it – not as part of the value which it possessed before the production process and the realization of the product – it follows that this surplus labour, which is included in the production costs of the product and forms the source of surplus value and hence of profit as well, does not figure as part of the production costs of capital. The latter are equal only to the values actually advanced by it, not including the surplus value appropriated in production and realized in circulation. The production costs from the standpoint of capital are therefore not the real production costs, precisely because surplus labour does not cost *it* anything. The excess of the price of the product over the price of the production costs gives it its profit. Thus profit can exist for capital even without the realization of the real production costs – i.e. the whole surplus labour set to work by capital. Profit – the excess over the advances made by capital – may be smaller than surplus value – the surplus of living labour gained in exchange by capital in excess of the objectified labour it has given in exchange for labour capacity. However, through the separation of interest from profit – which we will look at immediately – a part of the surplus value is posited as production cost even for productive capital itself. The confusion of *production costs* from the standpoint of capital with the amount of labour objectified in capital's product, surplus labour included, has given rise to statements such as that 'profit is not included in the natural price'. It is allegedly 'absurd to call the excess, or profit, a part of the expenditure'. (Torrens, IX, 30.) [32] This then leads to a mass of confusion; either by having profit not realized in, but rather arising from, exchange (which can always be the case only relatively, if one of the parties to the exchange does not obtain his equivalent), or by ascribing to capital some magic power which makes something out of nothing. Since the value posited in the production process realizes its price through exchange, the price of the product appears in fact determined by the sum of money which expresses an equivalent for the total quantity of labour contained in raw material, machinery, wages and in unpaid surplus labour. Thus price still appears here merely as a formal modification of value; as value expressed in money; but the magnitude of this price is presupposed in the production process of capital. Capital thereby appears as a determinant of price, so that price is determined by the advances made by capital + the surplus labour realized by it in the product. We shall see later that price, on the contrary, appears as determining profit. And, while here the total *real* production costs appear as determining price, price appears later as determining the production costs. So as to impose the inherent laws of capital upon it as external necessity, competition seemingly turns all of them over. *Inverts them.*

To repeat once more: the profit of capital does not depend on its magnitude; but rather, given an equal magnitude, on the relation between its component parts (the constant and the variable part); and then on the productivity of labour (which is expressed, however, in the above proportion, since, with diminished productivity, the same capital could not work up the same material with the same portion of living labour); on the turnover time, which is determined by the different proportions between fixed and circulating capital, different durability of fixed capital, etc. etc. (see above). The inequality of profit in different branches of industry with capitals of equal magnitudes is the condition and presupposition for their equalization through competition.

In so far as capital obtains raw material, instrument, labour, through exchange, buys them, its elements are themselves already present in the form of prices; already posited as prices; presupposed to it. The comparison of the market price of its product with the prices of its elements then becomes decisive for it. But this belongs only in the chapter on competition.

Thus the surplus value which capital posits in a given turnover period obtains the form of *profit* in so far as it is measured against the total value of the capital presupposed to production. While surplus value is measured directly by the surplus labour time which capital gains in the exchange with living labour. Profit is nothing but another form of surplus value, a form developed further in the sense of capital. Surplus value no longer regarded here as exchanged for capital itself in the production process; not for labour. Hence capital appears as capital, as presupposed value relating to itself, through the mediation of its own process, as posited, produced value, and the value posited by it is called *profit.*

The two immediate laws which this transformation of surplus value into the shape of profit yields for us are these: (1) *Surplus value expressed as profit always appears as a smaller proportion than surplus value in its immediate reality actually amounts to.* For, instead of being measured by a part of the capital, the part exchanged for living labour (a relation which turns out to be that of necessary to surplus labour), it is measured against the whole. Whatever may be the surplus value which a capital A posits, and whatever may be the proportion within A of c and v, the constant and the variable part of the capital, the surplus value s must appear smaller when measured against $c + v$ than when measured against its real measure, v. Profit, or – if it is regarded not as an absolute sum but rather, as is usually done, as a *proportion* (the rate of profit is profit expressed as the *relation in which* capital has posited surplus value) – the rate of profit never expresses the real rate at which capital exploits labour, but always a much smaller relation, and the larger the capital, the more false is the relation it expresses. The rate of profit could express the real rate of surplus value only if the entire capital were transformed solely into wages; if the entire capital were exchanged for living labour, i.e. if the *approvisionnement* alone existed, and if it not only existed not in the form of already produced raw material (which has happened in extractive industry), hence if not only the raw material were = 0, but if the means of production, also, whether in the form of instruments or in the form of developed fixed capital, were = 0. The latter case cannot occur on the basis of the mode of production corresponding to capital. If A = $c + v$, whatever the numerical value of s, then $s/(c + v) < s/v$. [33]

(2) The second great law is that the rate of profit declines to the degree that capital has already appropriated living labour in the form of objectified labour, hence to the degree that labour is already capitalized and hence also acts

increasingly in the form of fixed capital in the production process, or to the degree that the productive power of labour grows. The growth of the productive power of labour is identical in meaning with (a) the growth of relative surplus value or of the relative surplus labour time which the worker gives to capital; (b) the decline of the labour time necessary for the reproduction of labour capacity; (c) the decline of the part of capital which exchanges at all for living labour relative to the parts of it which participate in the production process as objectified labour and as presupposed value. The profit rate is therefore inversely related to the growth of relative surplus value or of relative surplus labour, to the development of the powers of production, and to the magnitude of the capital employed as [constant] capital within production. In other words, the second law is the *tendency of the profit rate to decline* with the development of capital, both of its productive power and of the extent in which it has already posited itself as objectified value; of the extent within which labour as well as productive power is capitalized.

Other causes which additionally act upon the rate of profit, which can depress it for longer or shorter periods, do not yet belong here. It is quite correct, as regards the production process as a whole, that the capital acting as material and as fixed capital not only is objectified labour, but must also be reproduced, and continuously reproduced, by new labour. Its presence assumes, therefore – the extent which its presence has attained assumes, therefore, the extent of the labouring population, population on a large scale, which in and for itself is the condition of all productive power – but this reproduction everywhere proceeds on the presupposition of the action of fixed capital and of raw material and of scientific power, both as such, and as appropriated within production and already realized within it. This point is to be developed in more detail only in the examination of accumulation.

It is clear, further, that although the part of capital exchanged for living labour declines in relation to the total capital, the total mass of living labour employed can increase or remain the same if capital grows in the same or a larger relation. Hence a constant growth in the population may accompany a relative decline in necessary labour. If capital A lays out 1/2 in c and 1/2 in v, while capital A′ lays out 3/4 in c and 1/4 in v, then capital A′ could employ 2/4 v for 6/4 c. But if it was originally = 3/4 c + 1/4 v, then it is now = 6/4 c + 2/4 v, or it grew by 4/4; i.e. it doubled. However, this relation also is to be examined more closely only in connection with the theory of accumulation and population. All in all we must not at this point be sidetracked by drawing the consequences which follow from the laws, and by turning them over in the mind from one angle or another.

The rate of profit is determined, then, not only by the relation of surplus labour to necessary labour, or by the relation in which objectified labour is exchanged for living labour, but by the overall relation of living labour employed to objective labour; by the portion of capital exchanged for living labour relative to the part which participates in the production process as objectified labour. This portion, however, declines in the same relation as surplus labour increases in relation to necessary labour.

Surplus value = *relation of surplus labour to necessary labour*

(Since the worker must reproduce the part of the capital which is exchanged for his labour capacity just as much as he must reproduce the other parts of the capital, the relation in which the capitalist gains from the exchange with labour capacity appears as determined by the relation of surplus labour to necessary labour. Originally this appears in such a way that the necessary labour only replaces his outlay. But since he lays out nothing other than labour itself – as is shown in reproduction – the relation can be expressed simply in this way – the relation of surplus value as the relation of surplus labour to necessary labour.)

Value of fixed capital *and its* productive power. *Durability of fixed capital, ditto. – The powers of society, division of labour etc.* cost *capital nothing. – Distinction between this and machinery (capitalist's* economy *in the employment of machinery). – Profit and surplus value*

<We have still to note in regard to fixed capital – and its durability, as one of its conditions which does not enter in from the outside: To the extent that the instrument of production is itself a value, objectified labour, *it does not contribute as a productive force.* If a machine which cost 100 working days

to make replaced only 100 working days, then it would in no way increase the productive power of labour and in no way decrease the cost of the product. The more durable the machine, the more often can the same quantity of product be created with it, or the more often can the circulating capital be renewed, its reproduction be repeated, and the smaller is the value-share (that required to replace the depreciation, the wear and tear of the machine); i.e. the more is the price of the product and its unit production cost decreased. However, we may not introduce the price relation at this point in the development. The reduction of the price as condition for conquest of the market belongs only to competition. It must therefore be developed in a different way. If capital could obtain the instrument of production at no cost, for 0, what would be the consequence? The same as if the cost of circulation = 0. That is, the labour necessary for the maintenance of labour capacity would be diminished, and thus surplus labour, i.e. surplus value, [increased], without the slightest cost to capital. Such an increase of the force of production, a piece of machinery which costs capital nothing, is the division of labour and the combination of labour within the production process. This assumes, however, work proceeding on a large scale, i.e. development of capital and wage labour. Another productive force which costs it nothing is scientific power. (It goes without saying that it must always pay a certain contribution for parsons, schoolmasters and scholars, whether the scientific power they develop is great or small.) But it can appropriate the latter only through the employment of machinery (and in part through the chemical process). The growth of population is a productive force of this kind, and it costs it nothing. In short, all the social powers developing with the growth of population and with the historic development of society cost it nothing. To the extent, however, that a substratum which itself exists in the form of objectified labour, i.e. is itself produced by labour, is required to employ them within the direct production process, hence to the extent that they are themselves values, it can appropriate them only through equivalents. Well. Fixed capital whose employment required more labour for its production or maintenance than it replaced would be a nuisance. The kind that would cost nothing, but merely needed to be appropriated by capital, would have the maximum value for capital. It follows from the simple proposition that machinery is most valuable for capital when its value = 0, that every reduction of its cost is a gain for capital. *While it is the tendency of capital, on one side, to increase the total value of the fixed capital,* [so], *at the same time,* [is its tendency] *to decrease the value of each of its fractional parts.* To the extent that fixed capital enters into circulation as value, it ceases to act as use value within the production process. Its use value is precisely that it increases the productive power of labour, decreases necessary labour, and increases relative surplus labour and hence surplus value. To the extent that it enters into circulation, its value is merely replaced, not increased. By contrast, the product, the circulating capital, is the vehicle of the surplus value, which is realized only when it steps outside the production process and into circulation. If machinery lasted for ever, if it did not itself consist of transitory material which must be reproduced (quite apart from the invention of more perfect machines which would rob it of the character of being a machine), if it were a *perpetuum mobile,* then it would most completely correspond to its concept. Its value would not need to be replaced because it would continue to last in an indestructible materiality. Since fixed capital is employed only to the extent that its value is smaller than the value it posits, it follows that, even if it never itself entered into circulation as value, the surplus value realized in the circulating capital would nevertheless soon replace the advances, and it would thus act to posit value after its costs for the capitalist, as well as the cost of the surplus labour he appropriates, were = 0. It would continue to act as a productive power of labour and at the same time be money in the third sense, constant value for-itself. Take a capital of £1,000. Let one-fourth be machinery; the sum of surplus value = 50. The value of the machinery then equal to 200. After 4 turnovers the machinery would be paid for. And, in addition, since the capital would continue to possess, in the machine, objectified labour to the amount of 200, then, beginning with the fifth turnover, it would be the same as if it made 50 on a capital which only costs it 800; hence 6 1/4% instead of 5%. As soon as fixed capital enters into circulation as value, its use value for the capital realization process ceases, or, it enters into it only as soon as the latter ceases. Hence, the more durable, the less it requires repair, total or partial reproduction, the longer its circulation time, the more does it act as productive power of labour, as capital; i.e. as objectified labour, which posits living surplus labour. The durability of fixed capital, which is identical with the circulation time of its value, or with the time required for its reproduction, arises from its concept itself, as its value-moment. (That in and for itself, as regards its *material* side only, it lies in the concept of the means of production is something which needs no elucidation.) The rate of surplus value is determined simply by the relation of surplus labour to necessary labour; the rate of profit is determined not only by the relation of surplus to necessary labour, but by the relation of the part of capital exchanged for living labour to the total capital entering into production.>

Profit as we still regard it here, i.e. as the profit of capital *as such,* not of an individual capital at the expense of another, but rather as the *profit of the capitalist class,* concretely expressed, *can never be greater than the sum of the surplus value.* As a sum, it is the sum of the surplus value, but it is this same sum of values as a proportion relative to the total value of the capital, instead of to that part of it whose value really grows, i.e. is exchanged for living labour. *In its immediate form, profit is nothing but the sum of the surplus value expressed as a proportion of the total value of the capital.*

Machinery and surplus labour. Recapitulation of the doctrine of surplus value generally

The transformation of surplus value into the form of profit, this method by which capital calculates surplus value, is necessary from the standpoint of capital, regardless of how much it rests on an illusion about the nature of surplus value, or rather veils this nature. *

> * It is easy to form the notion that machinery as such posits value, because it acts as a productive power of labour. But if machinery required no labour, then it would be able to increase the use value; but the exchange value which it would create would never be greater than its own costs of production, its own value, the labour objectified in it. It creates value not because it replaces labour; rather, only in so far as it is a means to increase surplus labour, and only the latter itself is both the measure and the substance of the surplus value posited with the aid of the machine; hence of labour generally.

If we look at a single worker's day, then the decrease of necessary labour relative to surplus labour expresses itself in the appropriation of a larger part of the working day by capital. The living labour employed here remains the same. Suppose that an increase of the force of production, e.g. employment of machinery, made 3 workers superfluous out of 6, each of whom worked 6 days a week. If these 6 workers themselves possessed the machinery, then each of them would thereafter work only half a day. Now, instead, 3 continue to work a whole day every day of the week. If capital were to continue to employ the 6, then each of them would work only half a day, but perform no surplus labour. Suppose that necessary labour amounted to 10 hours previously, the surplus labour to 2 hours per day, then the total surplus labour of the 6 workers was 2 × 6 daily, equal to a whole day, and was equal to 6 days a week = 72 hours. Each one worked one day a week for nothing. Or it would be the same as if the sixth worker had worked the whole week long for nothing. The 5 workers represent necessary labour, and if they could be reduced to 4, and if the one worker worked for nothing as before – then the relative surplus value would have grown. Its relation previously was = 1:6, and would now be 1:5. *The previous law, of an increase in the number of hours of surplus labour, thus now obtains the form of a reduction in the number of necessary workers.* If it were possible for this same capital to employ the 6 workers at this new rate, then the surplus value would have increased not only relatively, but absolutely as well. Surplus labour time would amount to 14 2/5 hours. 2 2/5 hours [each] performed by 6 workers is of course more than 2 2/5 performed by 5.

If we look at absolute surplus value, it appears determined by the absolute lengthening of the working day above and beyond necessary labour time. Necessary labour time works for mere use value, for subsistence. Surplus labour time is work for exchange value, for wealth. It is the first moment of industrial labour. The natural limit is posited – presupposing that the conditions of labour are on hand, raw material and instrument of labour, or one of them, depending on whether the work is merely extractive or formative, whether it merely isolates the use value from nature or whether it shapes it – the natural limit is posited by the number of simultaneous work days or of living labour capacities, i.e. by the labouring population. At this stage the difference between the production of capital and earlier stages of production is still merely formal. With kidnapping, slavery, the slave trade and forced labour, the increase of these labouring machines, machines producing surplus product, is posited directly by force; with capital, it is mediated through exchange.

Use values grow here in the same simple relation as exchange values, and for that reason this form of surplus labour appears in the slave and serf modes of production etc., where use value is the chief and predominant concern, as well as in the mode of production of capital, which is oriented directly towards exchange value, and only indirectly towards use value. This use value may be purely imaginary, as e.g. with the Egyptian pyramids, in short, with the works of religious ostentation which the mass of the nation in Egypt, India etc. was forced [to undertake]; or may be directed at immediate utility as e.g. with the ancient Etruscans.

In the second form of surplus value, however, as relative surplus value, which appears as the development of the workers' productive power, *as the reduction of necessary labour time relative to the working day,* and *as the reduction of the necessary labouring population* relative to the population (this is the antithetical form), in this form there directly appears the industrial and the distinguishing historic character of the mode of production founded on capital.

The forcible transformation of the greater part of the population into wage labourers, and the discipline which transforms their existence into that of mere labourers, correspond to the first form. Throughout a period of 150 years, e.g. from Henry VII on, the annals of English legislation contain the bloody handwriting of coercive measures employed to transform the mass of the population, after they had become propertyless and free, into free wage labourers. The dissolution of the monastic orders, the confiscation of church lands, the abolition of the guilds and confiscation of their property, the forcible ejection of the population from the land through the transformation of tillage into pasture, enclosures of commons etc., had posited the labourers as mere labour capacities. But they now of course preferred vagabondage, beggary etc. to wage labour, and had still to be accustomed forcibly to the latter. This is repeated in a similar fashion with the introduction of large industry, of factories operating with machines. Cf. Owen. [34]

Only at a certain stage of the development of capital does *the exchange of capital and labour become in fact formally free.* One can say that wage labour is completely realized in form in England only at the end of the eighteenth century, with the repeal of the law of apprenticeship.

The tendency of capital is, of course, to link up absolute with relative surplus value; hence *greatest stretching of the working day with greatest number of simultaneous working days, together with reduction of necessary labour time to the minimum, on one side, and of the number of necessary workers to the minimum, on the other.* This contradictory requirement, whose development will show itself in different forms as overproduction, over-population etc., asserts itself in the form of a process in which the contradictory aspects follow closely upon each other in time. A necessary consequence of them is the *greatest possible diversification of the use value of labour – or of the branches of production*—so that the production of capital constantly and necessarily creates, on one side, the *development of the intensity of the productive power of labour,* on the other side, the *unlimited diversity of the branches of labour,* i.e. thus the most universal wealth, in form and content, of production, bringing all sides of nature under its domination.

Capital pays nothing for the increase of the productive force arising by itself, in large-scale production, from division and combination of labour, from savings on certain expenses – conditions for the labour process – which *remain the same or diminish when labour is done in common, such as heating* etc., *industrial buildings* etc.; it obtains this increased productive power of labour free of charge. If the force of production increased simultaneously in the production of the different conditions of production, raw material, means of production and means of subsistence, and in the [branches of production] determined [by them], then their growth would bring about no change in the relation between the different component parts of the capital. If e.g. the productive force of labour grows simultaneously in the production of flax and of looms and of weaving itself (by division of labour), then a greater quantity of raw material etc. would correspond to the greater quantity woven in a day. In extractive work, e.g. the mining industry, it is not necessary for raw materials to increase when labour becomes more productive, since no raw material is used. To make harvests more productive, it is not even necessary for the number of instruments to have grown, but rather merely for them to be *concentrated* and for the work, *previously done fragmentarily by hundreds,* to be done *communally.* However, what is required for all forms of surplus labour is *growth of population;* of the labouring population for the first form; of population generally for the second, since it requires the development of science etc. Population, however, appears here as the basic source of wealth.

Relation between the objective conditions of production. Change in the proportion of the component parts of capital

But as we regard capital originally, raw material and instrument appear to come out of circulation, not to be produced by capital itself; just as, in reality, the individual capital obtains the condition of its production from circulation, although they are in turn produced by capital, but by another capital. From this follows, on one side, capital’s necessary tendency to subjugate production to itself on all sides; its tendency to posit the production of labour materials and of raw materials, as well as instruments, as likewise produced by capital, even if it is a different capital; the propagandistic tendency of capital. Secondly, however, it is clear that if *the objective conditions of production which it obtains from circulation remain unchanged in value,* i.e. if the same amount of labour objectifies itself in the same amount of use value, then a lesser part of the capital can be laid out for living labour, or, there is a *change in the proportion of the component parts of capital.* If the capital amounts to e.g. 100, raw material 2/5, the instrument 1/5, labour 2/5, and if, owing to a doubling of the productive force (division of labour), the same labour using the same instrument could work up double the raw material, then the capital would have to grow by 40; hence a capital of 140 would have to work; of which 80 in raw material, 20 in instrument, 40 for labour. Labour would now relate 40:140 (previously = 40:100); labour previously related as 4:10; now only as 4:14. Or, of the same capital of 100, now 3/5 would go for raw material, 1/5 for the instrument, and 1/5 for labour. The gain would be 20, as before. But surplus labour would be 60%, whereas it was 50 earlier. It now only takes 20 in labour for 60 in raw material and 20 in instrument. 80/20/100. A capital of 80 gives the capitalist a profit of 20. Now if the capital were to employ all the labour at this stage of production, it would have to grow to 160; namely 80 for raw material, instrument 40, and 40 for labour. This would give a surplus value of 40. At the earlier stage, where the capital of 100 gives a surplus value of only 20, a capital of 160 would give a surplus value of only 32, i.e. 8 less, and the capital would have to grow to 200 in order to produce the same surplus value of 40.

The following distinctions must be drawn: (1) Labour, increasing (or *intensity, speed of labour*), requires no greater advance in material or instrument of labour. E.g. the same 100 workers with instruments of the same value catch more fish, or till the soil better, or draw more ores from the mines or coal from the pits, or beat more leaf from the same amount of gold as a result of greater skill, better combination and division of labour etc., or waste less raw material, hence get further with the same value of raw materials. In this case then, if we assume either that their products enter into their own consumption, then their necessary labour time diminishes; they perform a greater amount of work at the same maintenance costs. Or, a smaller part of their labour is necessary for the reproduction of labour capacity. The necessary part of labour time diminishes relative to surplus labour time, and, although the value of the product remains the same 100 working days, the part going to capital, the surplus value, increases. If the total surplus worker was = 1/10, i.e. = 10 working days, and if it is now 1/5, then surplus labour time has grown by 10 days. The workers work 80 days for themselves and 20 for the capitalists, whereas in the first case 90 for themselves and only 10 for the capitalist. (This calculation by working days, and labour time as the only substance of value, shows itself in this open way where relations of bondage exist. With capital, covered up by money.) Of the newly created value, a greater portion accrues to capital. But the relations between the various component parts of the invariable capital remain the same, on this presupposition. That is, although the capitalist employs a greater mass of surplus labour, because he pays less wages, he does not employ more capital in raw materials and instruments. He gives a smaller part of objectified labour in exchange for the same amount of living labour, or the same amount of objectified for a greater amount of living labour. This possible only in extractive industry; in manufacturing, only in so far as there is greater economy in use of raw materials; further, where chemical processes increase the material, in agriculture; in the transporting industry.

(2) Productivity increases at the same time not only in the given branch of

production, but also in its conditions; in the case, namely, where raw material or instrument or both must be increased along with an increase in the intensity of labour, the increase of the number of products produced by labour in the same time. (The raw material need not cost anything, e.g. reeds for basket-making; free wood etc.) In this case the relation of capital remains the same. That is, with the growing productivity of labour the capital need not lay out a greater value in raw material and instruments.

(3) The increased productivity of labour requires a greater outlay of capital for raw material and instrument. If an unchanged number of workers has become more productive merely through division of labour etc., then the instrument remains the same; the raw material alone must grow; since the same labour time processes a greater amount of it in the same time; and, according to the presupposition, the productivity arose only from greater skill on the part of the workers, division and combination of labour etc. In this case the part of the capital exchanged for living labour not only diminishes (it remains the same if absolute labour time alone increases; decreases, if relative time grows) relative to the other component parts of capital, which remain the same, by an amount equal to its own decline, but likewise by an amount equal to their growth.

If it was

	Raw Material:	*Instrument:*	*Labour:*	*Surplus:*
Working days:	180	90	80	10
	411 3/7	90	70	20

in the first case: so that out of 90 working days, 10 are surplus working days; surplus labour 12 1/2%. In the second case, the relation of the raw material rose in the same proportion as the relation of surplus labour rose, compared to the first case.

While the growth of the surplus value in all cases presupposes growth of the population, in this case [it presupposes] additionally accumulation, or a greater capital entering into production. (This ultimately comes down to a larger population of workers occupied in the production of raw material.) In the first case the total part of the capital employed for labour forms 1/4 of the total capital, and relates to the constant part of the capital as = 1:3; in the second case capital employed for labour forms less than 1/6 of the total capital, and the total part of the capital employed for labour relates as less than 1:5 to the constant part of the capital. Hence, although *the increase of productive power resting on division and combination of labour rests on absolute increase of the labour power employed, it is necessarily linked with a decrease of the latter, relative to the capital which sets it in motion.* And while, in the first form, the form of *absolute surplus labour, the mass of labour employed must grow in the same relation as the capital employed,* in the *second case it grows in a lesser relation,* and, more precisely, *in inverse relation to the growth of the force of production.*

If the productivity of the soil doubled owing to employment of the latter method of agricultural labour, if the same amount of labour yielded 1 quarter of wheat instead of 1/2, then necessary labour would fall by 1/2, and capital could employ twice the number for the same wages. (This, if expressed in grain only.) But the capitalist would not need additional workers to work his land. Hence he will employ the same labour with half the previous wages; a part of his capital, the part earlier laid out in money, becomes free; the labour time employed has remained the same relative to the capital employed, but its surplus part has risen relative to the necessary part. If the relation of necessary labour to the total working day was = 3/4 of the working day or 9 hours, before, then it will now be equal to 3/8 or = 4 1/2 hours. In the first case the surplus value was 3 hours; in the second = 7 1/2.

The course of the process is this: With a given population of workers and length of the working day, i.e. length of the working day multiplied by the number of simultaneous working days, surplus labour can be increased only relatively, by means of greater productive power of labour, the possibility of which is already posited in the presupposed growth of the population and [its] training for labour (including thereby also a certain amount of free time for non-labouring, not directly labouring population, hence development of mental capacities etc.; mental appropriation of nature). Given a certain stage of the development of the productive forces, surplus labour can be absolutely increased only through transformation of a greater part of the population into workers, and increase of the number of simultaneous working days. The first process is *decrease of the relative working population, although it remains the same in absolute terms;* the second is *its increase.* Both tendencies necessary tendencies of capital. The unity of these contradictory tendencies, hence the living contradiction, only with machinery, which we will discuss in a moment. The first form obviously allows only a *small non-labouring population relative to the labouring one.* The second, since the quota of living labour required in it increases more slowly than the quota of capital employed, allows *a larger non-labouring population relative to the labouring one.*

During the formative stages of capital, where it obtains raw material and instrument, the conditions of the product, from circulation, it relates to these component parts and to their relations as given presuppositions. Although this appearance vanishes on closer examination, since all these moments appear as equally the products of capital, and since it would otherwise not have conquered the total conditions of its production, they nevertheless remain always in the same relation for the individual capital. Hence, one part of it can always be regarded as constant value, and only the part laid out in labour varies. These component parts do not develop evenly, but, as will be seen in competition, [it is] the tendency of capital to distribute the force of production evenly.

Since the growing productivity of labour would lead capital to encounter a barrier in the not-growing mass of raw material and machinery, industrial development takes the following course: the introduction of labour on a large scale, as well as the employment of machinery, begins in the branches which are closest to being production of raw materials for industry, raw material both for the material of labour and [for the] instrument, where the material of labour most closely approaches mere raw material. Thus, in spinning before in weaving, in weaving before printing etc. First of all in the production of metals, which are the chief raw material for the instruments of labour themselves. If the actual raw product which makes up the raw material for industry at the lowest stage cannot itself be rapidly increased – then refuge is sought in more rapidly increasable substitutes. (*Cotton* for linen, wool and silk.) The same happens for the necessaries of life in the substitution of potatoes for grain. The higher productivity in the latter case through production of a worse article containing fewer nourishing substances and hence cheaper organic conditions of the worker’s reproduction. The latter belongs in the examination of wages. In the discussion of the minimum wage, not to forget Rumford. [35]

Now we come to the third case of relative surplus labour as it presents itself in the employment of machinery.

<It has become apparent in the course of our presentation that value, which appeared as an abstraction, is possible only as such an abstraction, as soon as money is posited; this circulation of money in turn leads to capital, hence can be fully developed only on the foundation of capital, just as, generally, only on this foundation can circulation seize hold of all moments of production. This development, therefore, not only makes visible the historic character of forms, such as capital, which belong to a specific epoch of history; but also, [in its course] categories such as value, which appear as purely abstract, show the historic foundation from which they are abstracted, and on whose basis alone they can appear, therefore, in this abstraction; and categories which belong more or less to all epochs, such as e.g. money, show the historic modifications which they undergo. The economic concept of value does not occur in antiquity. Value distinguished only juridically from *pretium,* against fraud etc. The concept of value is entirely peculiar to the most modern economy, since it is the most abstract expression of capital itself and of the production resting on it. In the concept of value, its secret betrayed.>

What distinguishes surplus labour founded on machinery is the reduction of necessary labour time, which takes the form that fewer simultaneous working days are employed, fewer workers. The second moment, that the increase in productive power must be paid for by capital itself, is not free of charge. The means by which this increase in the force of production is set to work is itself objectified direct labour time, value, and, in order to lay hands upon it, capital must exchange a part of its value for it. It is easy to develop the introduction of machinery out of competition and out of the law of the reduction of production costs which is triggered [36] by competition. We are concerned here with developing it out of the relation of capital to living labour, without reference to other capitals.

If a capitalist annually employed 100 workers at spinning cotton, which annually cost him £2,400, and if he replaced 50 workers with a machine costing

£1,200, but in such a way that the machine would likewise be worn out within the year and have to be replaced again at the beginning of the second year, then he would obviously have gained nothing; nor could he sell his product more cheaply. The remaining 50 workers would do the same work as 100 did earlier; each individual worker's surplus labour would have increased in the same relation as their number had diminished, hence would have remained the same. If previously it was = 200 hours of work daily, i.e. 2 hours for each of the 100 working days, then it would now likewise be = 200 hours of work, i.e. = 4 for each of the 50 working days. Relative to the worker, his surplus time would have increased; for capital the matter would be unchanged, since it would now have to exchange 50 working days (necessary and surplus time together) for the machine. The 50 days of objectified labour which it exchanged for machinery would only give him an equivalent, hence no surplus time, as if it had exchanged 50 days of objectified labour for 50 living ones. This would be replaced, however, by the surplus labour time of the remaining 50 workers. If the form of exchange is stripped off, the matter would be the same as if the capitalist employed 50 workers whose entire working day were necessary labour only, and 50 additional ones whose working day made good this 'loss'. But posit now that the machine cost only £960, i.e. only 40 working days, and that the remaining workers produce 4 hours of surplus labour time each, as before, i.e. 200 hours or 16 days, 4 hours (16 1/3 days), then the capitalist would have saved £240 on outlays. While he gained only 16 days 4 hours with his previous outlay of 2,400, he would now likewise gain 200 hours of work on an outlay of 960. 200 is to 2,400 as 1:12; while 200:2,160 = 20:216 = 1:10 4/5. Expressed in days of work, in the first case he would gain 16 days 4 hours per 100 working days, in the second, the same amount on 90; in the first, on 1,200 hours of work daily, 200; in the second, on 1,080. 200:1,200 = 1:6, 200:1,080 = 1:5 2/3. In the first case the individual worker's surplus time = 1/6 working day = 2 hours. In the second case = 2 6/27 hours per worker. Furthermore, with the employment of machinery, the part of the capital which was previously employed in instruments must be deducted from the additional cost caused by the machinery.

Money and fixed capital: *presupposes certain amount of wealth.*

(Economist.) – *Relation of fixed capital and circulating capital. Cotton-spinner* (Economist)

<The money circulating in a country is a *certain portion of the capital* of the country, absolutely withdrawn from productive purposes, in order to facilitate *or increase the productiveness of the remainder.* A certain amount of wealth is, therefore, as necessary, in order to adopt gold as a circulating medium, *as it is to make a machine, in order to facilitate any other production.' (Economist,* Vol. V, p. 520.)> <'What is the practice? A manufacturer obtains £500 from his banker on Saturday, for wages; he distributes these among his workers. On the same day the majority of money is brought to the shopkeepers, and through them returned to their various bankers.' (loc. cit. p. 575.)>

<'A cotton spinner, with a capital of £100,000, who laid out £95,000 for his mill and machinery, would soon find he wanted means to buy cotton and pay wages. His trade would be hampered and his finances deranged. And yet men expect that a nation, which has recklessly sunk the bulk of its available means in railways, should nevertheless be able to conduct the infinite operations of manufacture and commerce.' (loc. cit. p. 1271.)>

Slavery and wage labour (Steuart). – Profit upon alienation. *Steuart*

'Money ... *an adequate equivalent for any thing alienable.'* (J. Steuart.) (p. 13) (Vol. I, p. 32, ed. Dublin, 1770.)

<'In the old times to make mankind labour beyond their wants, to make one part of a state work, to maintain the other gratuitously, to be brought about only through slavery ... If mankind be not forced to labour, they will only labour for themselves; and if they have few wants, there will be few [who] labour. But when states come to be formed and have occasion for idle hands to defend them against the violence of their enemies, food at any rate must be procured for those who do not labour; and as, by the supposition, the wants of the labourers are small, a method must be found to increase their labour above the proportion of their wants. For this purpose slavery was calculated ... Here then was a violent method of making men laborious in raising food; ... men were then

forced to labour because they were slaves of others; men are now forced to labour because they are slaves to their own wants.’ (Steuart, Vol. I, p. 38–40.) ‘It is the *infinite variety of wants,* and of the *kinds of commodities* necessary to their gratification, which alone renders the passion for wealth indefinite and insatiable.’ (Wakefield *on* A. Smith, p. 64 note.)> [37]

‘Machines I consider as a method of augmenting (virtually) the number of industrious, without the expense of feeding an additional number.’ (Steuart, Vol. I, p. 123.) ‘When manufacturers get together in bodies, they depend not directly upon *consumers,* but upon *merchants.’* (Steuart, Vol. I, p. 154.) ‘The abusive agriculture is no *trade,* because it applies no *alienation,* but is purely a method of subsisting.’ (loc. cit. p. 156.) *‘Trade* is an operation, by which the wealth, or work, either of individuals, or of societies, may be exchanged, by a set of men called *merchants,* for an equivalent, proper for supplying every want, without any interruption to industry, or any check upon consumption.’ (Steuart, I, p. 166.) ‘While wants continue simple and few, a workman finds time enough to distribute all his work; when wants become more multiplied, men must work harder: *time becomes precious;* hence trade is introduced. The merchant as mediator between the workman and consumer.’ (loc. cit. p. 171.) ‘Money the *common* price of all things.’ (loc. cit. p. 177.) ‘Money represented by the merchant. To the consumers, the merchant represents the totality of manufacturers, towards the latter, the totality of consumers, and to both classes his credit supplies the use of money. He represents wants, manufacturers and money by turns.’ (loc. cit. p. 177, 178.) (Steuart, see Vol. I, p. 181–3, regards profit as distinct from *real value,* which he defines very confusedly (has production costs in mind) as the amount of objectified labour (what a workman can perform in a day etc.), necessary expense of the workmen, price of the raw material, as *profit upon alienation* fluctuating with demand.) (With Steuart the categories still vary greatly; they have not yet become fixed, as with A. Smith. We just saw that *real value* identical with production costs, in which, besides the labour of the workmen and the value of the material, wages, also, confusingly, figure as a separate component part. At another point he takes the *intrinsic value* of a commodity to mean the value of its raw material or the raw material itself, while, by *useful value,* he understands the labour time employed on it. ‘The first is something real in itself; e.g. the silver in a silver

lattice-work. The *intrinsic worth* of a silk, woollen or linen manufacture is less than the primitive value employed, because it is rendered almost unserviceable for any other use but that for which the manufacture is intended; the *useful value by contrast must be estimated according to the labour it has cost to produce it. The labour employed in the modification represents a portion of a man's time,* which having been usefully employed, *has given a form to some substance* which has rendered it useful, ornamental, or in short, fit for man, mediately or immediately.' (p. 361, 362, Vol. I loc. cit.) (The real use value is the form given to the substance. But this form itself is only static labour.) 'When we suppose a common standard on the price of any thing, we must suppose the alienation of it to be frequent and familiar. In countries where simplicity reigns, ... it is hardly possible to determine any standard for the price of articles of first necessity ... in such states of society the articles of food and necessaries are hardly found in commerce: no person purchases them; because the principal occupation of everybody is to procure them for himself ... Sale alone can determine prices, and frequent sale can only fix a standard. Now the frequent sale of articles of the first necessity marks a distribution of inhabitants in labourers and free hands' etc. (Vol. I, p. 395 seq. loc. cit.) (The doctrine of the determination of prices by the mass of the circulating medium first advanced by Locke, repeated in the *Spectator,* 19 October 1711, developed and elegantly formulated by Hume and Montesquieu, its basis raised to its formal peak by Ricardo, and with all its absurdities in practical application to the banking system, by Loyd, Colonel Torrens etc.). Steuart polemicizes against it, and his development materially anticipates more or less everything later advanced by Bosanquet, Tooke, Wilson. (Notebook, p. 26.) [38] (He says among other things as historic illustration: 'It is a fact that at the time when Greece and Rome abounded in wealth, when every rarity and the work of choicest artists was carried to an excessive price, an ox was bought for a mere trifle and grain was cheaper perhaps than ever it was in Scotland ... The demand is proportioned, not to the number of those who consume, but of those who buy; now those who consume are all the inhabitants, but those who buy are only the few industrious who are free ... In Greece and Rome, slavery: Those who were fed by the labour of their own slaves, the slaves of the state, or by grain distributed free of charge among the people, had no occasion to go to the market: they did not enter into competition with the buyers … The few manufacturers then known made wants in general less extensive; consequently, the number of the industrious free was small, and *they* were the only persons who *could* have occasion to purchase food and necessaries: consequently, the competition of the buyers must have been small in proportion, and price low; further the markets were supplied partly from the surplus produced on the lands of the great men, laboured by slaves; who being fed from the lands, the surplus cost in a manner nothing to the proprietors; and since the number of those who had occasion to buy, very small, this surplus was sold cheap. Also, the grain distributed to the people free of charge must necessarily have held the market down, etc. By contrast, for a fine mullet or an artist, etc. great competition and hence prices rising extraordinarily. The luxury of those times, though excessive, was confined to a few, and as money, in general, circulated but slowly through the hands of the multitude, it was constantly stagnating in those of the rich who found no measure, but their own caprice, in regulating the prices of what they wished to possess.') (26, 27, Notebook. Steuart.) [39] '*Money of account* is nothing but an arbitrary scale of equal parts, invented for measuring the respective value of things vendible. Money of account quite different from *money-coin,* which is price, and could exist, even if there were no substance in the world which was the proportional equivalent for all commodities.' (Vol. II, p. 102.) 'Money of account does the same service for value as things like minutes, seconds etc. do for angles, or scales for geographical maps etc. In all these inventions some denomination is always taken for the unit.' (loc. cit.) 'The usefulness of all those inventions being solely confined to the marking of *proportion.* Just so, the unit in money can have no invariable determinate proportion to any part of value, i.e. it cannot be fixed to any particular quantity of gold, silver or any other commodity whatsoever. The unit once fixed, we can, by multiplying it, ascend to the greatest value' etc. (p. 103.) 'So money a scale for measuring value.' (p. 102.) 'The value of commodities, therefore, depending upon a general combination of circumstances relative to themselves and to the fancies of men, their value ought to be considered as changing only with respect to one another; consequently, any thing which troubles or perplexes the ascertaining those *changes of proportion by the means of a general, determinate and* *invariable scale,* must be hurtful to trade and a clog upon alienation.' (loc. cit.) 'It is absolutely necessary to distinguish between *price* (i.e. coin) considered as a measure and *price* considered as an equivalent for value. The metals do not perform both functions equally well ... *Money is an ideal scale of equal parts.* If it be demanded what ought to be the standard of value of one part? I answer by putting another question: What is the standard length of a degree, a minute, a second? It has none – but so soon as one part becomes determined, by the nature of a scale, all the rest must follow in proportion.' (p. 105.) 'Examples of this ideal money are the bank money of Amsterdam and the Angola money on the African coast. – The bank money stands invariable like a rock in the sea. According to this ideal standard are the prices of all things regulated.' (p. 106, 107 seq.)

In Custodi's anthology of the Italian economists, *Parte Antica, Tomo III:* Montanari (Geminiano), *Della moneta,* written about 1683, [40] says of the 'invention' of money: 'Intercourse between nations spans the whole globe to such an extent that one may almost say all the world is but a single city in which a permanent fair comprising all commodities is held, so that by means of money all the things produced by the land, the animals and human industry can be acquired and enjoyed by any person in his own home. A wonderful invention!' (p. 40.) 'But, since it is another peculiarity of measures that they enter into such a relation with the things measured that in a certain manner the thing measured becomes the measure of the measuring unit, it follows that, just as motion is the measure of time, time may be the measure of the motion itself; hence it occurs that not only are the coins measures of our wants, but also our wants are, reciprocally, the measure of the coins themselves and of value.' (p. 41, 42.) 'It is quite clear that the greater the number of coins circulating in commerce within the confines of a given district, in proportion to the marketable goods there are in that place, the more expensive will they be. Can a thing be said to be expensive because it is worth a large quantity of gold in countries where gold is abundant? Should not the gold itself, which is estimated as of the same quantity as another thing which comes to be considered elsewhere as cheap, be rather described as cheap in that case?' (p. 48.)

'100 years earlier the chief feature in the commercial policy of nations was the *amassing* of gold and silver, as a kind of wealth par excellence.' (p. 67.)

(Gouge, Wm. *A Short History of Paper Money and Banking in the United States. Philadelphia,* 1833.) *(Barter in United States (see* Gouge Notebook VIII, p. 81 seq.): ‘In Pennsylvania as in the other colonies, significant traffic was carried on by barter … as late as 1723 in Maryland, an act was passed making tobacco a legal tender at one penny a pound, and Indian corn at 20d. a bushel.’ (p. 5.) (Part II.) Soon however, ‘their trade with the West-Indies and a clandestine commerce with the Spanish made silver so plentiful, that in 1652 a mint was established in New England for coining shillings, sixpences and threepenny pieces.’ (p. 5.) (loc. cit.) ‘Virginia in 1645 forbade dealings by barter, and established the Spanish piece of 8 to 6s. as the standard currency of the colony (the Spanish dollar) … The other colonies affixed different denominations to the dollar … The money in account was everywhere nominally the same as in England. The coin of the realm was especially Spanish and Portuguese’ etc. cf. p. 81 Notebook VIII). (p. 6. By an act of Queen Anne an attempt was made to put an end to this confusion.)

Wool industry in England since Elizabeth* (Tuckett). – *Silk-manufacture (Same). Ditto Iron. Cotton

Tuckett: *A History of the Past and Present State of the Labouring Population* etc., 2 vols., London, 1846.

‘Wool manufactures: During Elizabeth’s time the *clothier* occupied the place of the *mill-owner or manufacturer;* he was the capitalist who brought the wool, and delivered it to the weaver, in portions of about 12 pounds, to be made into cloth. At the beginning, manufacture was *confined to cities* and *corporate and market-towns,* the inhabitants of the villages making little more than [sufficed] for the use of their families. Later, in non-corporate towns favoured by local advantages, and also in country places by farmers, graziers and husbandmen, who commenced making cloth for sale, as well as for domestic use.’ (The cruder sorts.) ‘In 1551 a statute was passed, restricting the number of looms and apprentices which might be held by clothiers and weavers residing out of cities; and that no country weaver should have a tucking mill, nor any tucker a loom. By a law of the same year, all weavers of broad cloth had to undergo an apprenticeship of 7 years. Nevertheless, *village manufacture,*

as an *object of mercantile profit,* took firm root. 5 and 6 *Edward VI,* c. 22, a statute, prohibits the use of *machinery* … The Flemish and Dutch thus maintained superiority in this manufacture until the end of the seventeenth century … In 1668 the Dutch loom was introduced from Holland.' (p. 138–41.) *'Owing to the introduction of machinery, in 1800 one person could do as much work as 45 in the year 1785.* In the year 1800 the capital invested in mills, machinery etc. appropriate for the woollen trade was not less than *6 million pounds sterling and the total number of persons of all ages occupied in England in this branch was 1,500,000.'* (p. 142–3.) Thus the productive power of labour grew 4,600%. But, firstly, this number only about 1/6 of the fixed capital alone; relative to the total capital (raw material etc.) perhaps only 1/20. 'Hardly any manufacture had such an advantage from the improvements in science as the art of dyeing cloth through the application of the *laws of chemistry.'* (loc. cit. p. 144.)

Silk manufacture. Until the beginning of the eighteenth century, 'the art of *silk throwing* most successful in Italy, where machinery of a particular description adopted to this purpose. In 1715 John Lombe, one of three brothers who had a business as throwers and silk-merchants, travelled to Italy and was able to obtain a model in one of the mills … A silk mill, with the improved machinery, erected in 1719 in Derby by Lombe and his brothers. This mill contained 26,586 wheels, all turned by one water wheel … Parliament gave him £14,000 for throwing open the secret to the trade. This mill came nearer to the idea of a modern factory than any previous establishment of the kind. The machine had 97,746 wheels, movements, and individual parts working day and night, all of which were moved by one large water wheel and were governed by one regulator: and it employed 300 persons to attend and supply it with work.' (133–4.) (No spirit of invention showed itself in the English silk trade; first introduced by the weavers of Antwerp, who fled after the sacking of the town by the Duke of Parma; then different branches by the French refugees 1685–92.)

In 1740, 1,700 tons of iron were produced by 59 high furnaces; 1827: 690,000 by 284. Furnaces thus increased = 1:4 48/49; less than quintupled; the tons = 1:405 15/17. (Comp. on the relation over a series of years loc. cit. Notebook p. 12.) [41]

Glass manufacturing, among other things, best shows how dependent [is] the progress of science on manufactures. On the other side e.g. the invention of quadrants arose from the needs of navigation, parliament offered a prize for inventions.

8 cotton machines, which cost £5,000 in 1825, were sold in 1833 for £300. (On cotton spinning, see loc. cit. p. 13, Notebook.) [42]

'A first rate cotton spinning factory cannot be built, filled with machinery, and fitted with gas work and steam engine, under £100,000. A steam engine of one hundred horse power will turn 50,000 spindles, which will produce 62,500 miles of fine cotton-thread per day. In such a factory, 1,000 persons will spin as much thread as 250,000 persons could without machinery. McCulloch estimates the number in Britain at 130,000.' (p. 218, loc. cit.)

Origin of free wage labour. *Vagabondage.* Tuckett

'Where there are no regular roads, there can hardly be said to be a community; the people could have nothing in common.' (p. 270. Tuckett loc. cit.)

'Of the produce of the earth, useful to men, 99/100 are the produce of men.' (loc. cit. p. 348.)

'When slavery or life-apprenticeship was abolished, the labourer became his own master and was left to his own resources. But if without sufficient employment etc., men will not starve whilst they can beg or steal; consequently the first character the poor assumed was that of thieves and mendicants.' (p. 637 note, Vol. II, loc. cit.) 'One remarkable distinction of the present state of society, since Elizabeth, is that her poor law was especially a law for the enforcement of industry, intended to meet the mass of vagrancy that grew out of the suppression of the monasteries and the transition from slavery to free labour. As example, the 5th act of Elizabeth, directing households using half a plough of land in tillage, to require any person they might find unemployed, to become their apprentice in husbandry, or in any art or mystery; and, if unwilling, to bring him before a justice, who was almost compelled to commit him to ward until he consented to be bound. Under Elizabeth, out of every 100 people, 85 were required for the production of food. At present, not a lack of industry, but a profitable employment ... *The great difficulty then was* to overcome the propensity of idleness and vagabondage, not to procure them remunerative occupation. During this reign there were several acts of the legislature to enforce the idle to labour.’ (p. 643, 644. Vol. II, loc. cit.)

‘Fixed capital, when once formed, ceases to affect the demand for labour, but during its formation it gives employment to just as many hands as an equal amount would employ, either of circulating capital, or of revenue.’ (p. 56. John Barton, *Observations on the Circumstances which Influence the Condition of the Labouring Classes of Society,* London, 1817.)

Blake *on accumulation and rate of profit. (Shows that prices etc. not indifferent because a class of mere consumers does not at the same time consume and reproduce.) – Dormant capital*

‘The community consists *of two classes of persons,* one, which consumes and reproduces, the other, which consumes without reproduction. If the entire society consisted of producers, then of little consequence at what price they exchanged their commodities among one another; but those who are only consumers form too numerous a class to be overlooked. Their power of demanding arises from seats, mortgages, annuities, professions and services of various descriptions rendered to the community. The higher the price at which the class of consumers can be made to buy, the greater will be the profit of the producers upon the mass of commodities which they sell to them. Among these purely consuming classes, the government takes up the most prominent station.’ (W. Blake, *Observations on the Effects Produced by the Expenditure of Government during the Restriction of Cash Payments,* London, 1823, p. 42, 43.) In order to show that the capital lent to the state is not necessarily such as was previously employed productively – and we are concerned here only with the admission that a part of capital is always dormant – Blake says: ‘The error lies in the supposition (1) that the whole capital of the country is fully employed; (2) *that there is immediate employment for successive accumulations of capital as it accrues from saving.* I believe there are at all times some portions of capital devoted to undertakings that yield very slow returns and slender profits, and some portions lying wholly dormant in the form of goods, for which there is no sufficient demand … Now, if these dormant portions and savings could be transferred into the hands of government in exchange for its annuities, they would become sources of new demand, without encroaching upon existing capital.' (p. 54, 55 loc. cit.) '*Whatever amount of produce is withdrawn from market by the demand of the saving capitalist, is poured back again, with addition, in the goods that he reproduces.* The government, by contrast, takes it away from consumption without reproduction ... Where savings are made from revenue, it is clear that the person entitled to enjoy the portion saved is satisfied without consuming it. It proves that the industry of the country is capable of raising more produce than the wants of the community require. If the quantity saved is employed as capital in reproducing a value equivalent to itself, together with a profit, this new creation, when added to the general fund, can be drawn out by that person alone who made the savings, i.e. by the very person who has already shown his disinclination to consume ... If everyone consumes what he has a right to consume, there must of necessity be a market. Whoever saves from his revenues, foregoes this right, and his share remains undisposed of. Should this spirit of economy be general, the market is necessarily overstocked, and it must depend on the degree, to which this surplus accumulates, whether it can find new employments as capital.' (56, 57.) (Cf. this work generally in the section on *accumulation.)* (Cf. Notebook p. 68 and p. 70, where it is shown that the rate of profits and wages rose owing to *prices,* caused by war demand, without any respect 'to the quantity of land taken last into cultivation'.) 'During the revolutionary war the market rate of interest rose to 7, 8, 9 and even 10%, although during the whole time lands of the lowest quality were cultivated.' (loc. cit. p. 64–6.) 'The rise of interest to 6, 8, 10 and even 12% proves the rise of profit. The depreciation of money, supposing it to exist, could not change the relation of capital and interest. If £200 are worth only £100; £10 interest worth only £5, whatever affected the value of the principal would equally affect the value of profits. It could not alter the relation between the two.' (p. 73.) 'Ricardo's reasoning, that the price of wages cannot make the prices of commodities rise, does not apply to a society *where a large class are not producers.'* (loc. cit.) 'More than the just share is obtained by the producers at the expense of that portion, which of right belongs to the class who are only consumers.' (74.) This of course important, since capital exchanges not only for capital, but also for revenue, and each capital can itself be eaten up as revenue.

Still, this does not affect the determination of profit in general. Under the various forms of profit, interest, rent, pensions, taxes etc., it may be distributed (like a part of wages even) under different titles among different classes of the population. They can never divide up among them more than the total surplus value of the total surplus product. The ratio in which they distribute it is of course economically important; [but] does not affect the question before us.

‘If the circulation of commodities of 400 million required a currency of 40 million, and this proportion of 1/10 were the due level, then, if the value of the commodities to be circulated grows to 450 million, from natural causes, the currency, in order to continue at its level, would have to grow to 45 million, or the 40 million must be made to circulate with such increased rapidity, by banking or other improvements, as to perform the functions of 45 million ... such an augmentation, or such rapidity, the consequence and not the cause of the increase of prices.’ (W. Blake. loc. cit., p. 80 seq. cf. Notebook p. 70.)

‘The upper and middle class of Rome gained great wealth by Asiatic conquest, but not being created by commerce or manufactures, it resembled that obtained by Spain from her American colonies.’ (p. 66 Vol. I, Mackinnon, *History of Civilisation,* London, 1846, Vol. I.)

Domestic agriculture at the beginning of the sixteenth century. **Tuckett**

‘In the fifteenth century, Harrison asserts’ (see also Eden), [43] ‘that the farmers are barely able to pay their rents without selling a cow, or a horse, or some of their produce, although they paid at the most £4 for a farm ... The farmer in these times consumed the chief part of the produce to be raised, his servants taking their seats with him at his table ... *The principal materials for clothing were not bought, but were obtained by the industry of each family. The instruments of husbandry* were so simple that many of them were made, or at least kept in repair, by the farmer himself. Every yeoman was expected to know how to make yokes or bows, and plough gear; *such work* employed their winter evenings.’ (p. 324, 325 loc. cit. Tuckett, Vol. II.)

Profit. Interest. Influence of machinery on the wage fund.

Westminster Review

Interest and Profit: 'Where an individual employs his own savings productively, the remuneration of his time and skill – *agency for superintendence (profit* further includes the risk to which his capital may have been exposed in his particular business); and the remuneration for the productive employment of his savings, *Interest.* The whole of this remuneration, *Gross Profit;* where an individual employs the savings of another, he obtains the agency only. Where one individual lends his savings to another, only the *interest* or the *net profit.' (Westminster Review,* January 1826, p. 107, 108.) Thus here interest = *net profit = remuneration for the productive employments of savings;* the actual profit the remuneration for the *agency for superintendence* during his productive employment. The same philistine says: 'Every improvement in the arts of production, that does not disturb the proportion between the portions devoted to capital and not devoted to the payment for wages, is attended with an increase of employment to the labouring classes: every fresh application of machinery and horse labour is *attended with an increase of produce and consequently of capital;* to whatever extent it may diminish the *ratio* which that part of the national capital forming the fund for the payment of wages bears to that which is otherwise employed, its tendency is not to diminish but to increase the *absolute amount of that fund* and hence to increase the quantity of employment.' (loc. cit. p. 123.)

[*Money as measure of values and yardstick of prices. Critique of theories of the standard measure of money.*]

The role of money as *measure,* as well as, secondly, the fundamental law that the mass of the circulating medium, at a definite velocity of circulation, is determined by the prices of the commodities and by the mass of commodities circulating at definite prices, or by the total price, the aggregate amount of commodities, which is itself in turn determined by two circumstances: (1) the level of the commodity price; (2) the mass of circulating commodities at definite prices; further, (3) the law that money as medium of circulation becomes coin, mere vanishing moment, mere *symbol* of the values it exchanges – all this leads to more particular aspects which we shall develop only when and in so far as they coincide with more complicated economic relations, credit circulation, exchange rate etc. It is necessary to avoid all detail, and where detail must be brought in, it is to be brought in only at the point where it loses the elementary character.

First of all, money circulation, as the most superficial (in the sense of: driven out onto the surface) and the most abstract form of the entire production process, is in itself quite without content, except in so far as its own formal distinctions, precisely the simple aspects developed in section II, make up its content. It is clear that simple money circulation, regarded in itself, is not bent back into itself, [but] consists of an infinite number of indifferent and accidentally adjacent movements. The coin, e.g., may be regarded as the point of departure of money circulation, but there is no law of any reflux back to the coin except for depreciation through wear and tear, which necessitates melting-down and new issue of coins. This concerns only the material side and does not at all form a moment of circulation itself. Within circulation itself, the point of return may be different from the point of departure; in so far as it bends back into itself, money circulation appears as the mere appearance of a circulation going on behind it and determining it, e.g. when we look at the money circulation between manufacturer, worker, shopkeeper and banker. Furthermore, the factors which affect the mass of commodities thrown into circulation, the rise and fall of prices, the velocity of circulation, the amount of simultaneous payments etc., are all circumstances which lie *outside* simple money circulation itself. They are relations which express themselves in it; it provides the names for them, as it were; but they are not to be explained by its own differentiation. Different metals serve as money, and they have a different and changing value relation to one another. Thus the question of the double standard etc. enters, which takes on world-historical forms. But it takes them on, and the double standard itself enters, only through external trade, hence, to be usefully examined, supposes the development of much higher relations than that of the simple money relation.

Money as the *measure* of value is not expressed in amounts of bullion, but rather in accounting money, arbitrary names for fractional parts of a specific amount of the money-substance. These names can be changed, the relation of the coin to its metallic substance can be changed, while the name remains the same. Hence counterfeiting, which plays a great role in the history of states. Further, the different kinds of money in various countries. This question [is of] interest only in exchange rate. [44]

Money is a *measure* only because it is labour time materialized in a specific substance, hence itself *value,* and, more particularly, because this specific materiality counts as its general objective one [*allgemeingegenständliche*], as the materiality of labour time as such, as distinct from its merely particular incarnations; hence because it is an *equivalent.* But since, in its function as *measure,* money is only an imagined point of comparison, only needs to exist ideally – only the ideal transposition of commodities into their general value-presence takes place –; since, further, in this quality as measure it figures first as accounting coin, and I say a commodity is worth so many shillings, francs etc., when I transpose it into money; this has given rise to the confused notion of an *ideal measure,* developed by Steuart and refurbished at various periods, even recently, in England, as a profound discovery. Namely in this sense, that the names, pound, shillings, guinea, dollar etc., which count as accounting units are not specific names for specific quantities of gold, silver etc., but merely arbitrary points of comparison which do not themselves express value, no definite quantity of objectified labour time. Hence the whole nonsense about fixing the price of gold and silver – price understood here as the name by which fractional parts are called. An ounce of gold now divided into £3 17s. 10d. This is called fixing the price; it is, as Locke correctly remarks, only fixing the name of fractional parts of gold and silver etc. Expressed in itself, gold, silver is naturally equal to itself. An ounce is an ounce, whether I call it £3 or £20. In short, this *ideal measure* in Steuart's sense means this: if I say commodity A is worth £12, commodity B 6, commodity C 3, then their relation to one another = 12:6:3. Prices express only the relations in which they are exchanged for one another. 2B are exchanged for 1A and 1 1/2B for 3C. Now, instead of expressing the relation of A, B, C in real money, money which itself has value, is value, could I not, instead of the £ which expresses a specific mass of gold, just as well take any name you like, without content (this means, here, *ideally*), e.g. mackerels? A = 12 mackerels; B = 6M, C = 3M. This word M is here only a name, without any relation to a content belonging to itself. Steuart's example with a degree, line, second, proves nothing; for although degree, line, second have changing magnitudes, they are not merely names, but rather always express the fractional part of a specific magnitude of space or of time. They thus have in fact a substance. The fact that money in the role of measure functions only as something *imagined* is here transformed into it supposedly being any imagined thing you like, a mere *name,* namely a name for the numerical value-relation. In that case, however, it would be correct to express no names at all, but merely a numerical relation, for the whole affair comes down to this: I obtain 6B for 12A, 3C for 6B; this relation can also be expressed in this way, A = 12x, B = 6x, C = 3x, where the x is itself only a name for the relation of A:B and B:C. The mere, unnamed numerical relation would not do. For A:B = 12:6 = 2:1, and B:C = 6:3 = 2:1. Hence C = 1/2. Hence B = 1/2, hence B = C. Hence A = 2 and B = 2; hence A = B.

Let me take any price list, e.g. potash, 35s. the ton; cocoa, lb., 60s.; iron (bars) (p. ton) 145s. etc. In order to have the relation of these commodities to one another, not only can I forget the silver in the shilling; the numbers alone, 35, 60, 145 suffice to define the reciprocal value relations of potash, cocoa, iron bars. Undenominated numbers now suffice; and not only can I give their unit, 1, any name, regardless of any value; I need not give it any name at all. Steuart insists that I must give it one or another name, but that this name then, as mere arbitrary name of the unit, as mere *marking of proportion* itself, cannot be fixed to any portion of the quantity of gold, silver or any other commodity.

With every measure, as soon as it serves as point of comparison, i.e. as soon as the different entities to be compared are put into a numerical relation to the measure as unit, and are now related to one another, the nature of the measure becomes irrelevant and vanishes in the act of comparison itself; the unit of measure has become a mere unit of numbers; the quality of this unit has vanished, e.g. that it is itself a specific magnitude of length or of time or of an angle. But is it only when the different entities are already presupposed as measured that the unit of measure *marks only proportion between them,* thus e.g. in our case the proportion of their values. The accounting unit not only has different names in different countries; but is the name for different fractional parts of an ounce of gold, e.g. But the exchange rate reduces all of them to the same unit of weight of gold or silver. Thus if I presuppose the various magnitudes of commodities, e.g. as above, = 35s., 60s., 145s., then, to compare them, since the 1 is presupposed as equal in all of them, since they have been made commensurable, it is wholly superfluous to bring in the observation that s. is a specific quantity of silver, the name for a specific amount of silver. But, as mere numerical magnitudes, as amounts of any unit of the same name, they only become comparable to one another, and only express proportions towards one another, when each individual commodity is measured with the one which serves as unit, as measure. But I can only measure them against one another, only make them commensurable, if they have a unit – the latter is the labour time contained in both. The measuring unit must therefore [be] a certain quantity of a commodity in which a quantity of labour is objectified. Since the same quantity of labour is not always expressed in the same quantity of e.g. gold, it follows that the value of this measuring unit itself variable. But, in so far as money is regarded only as measure, this variability is no obstacle. Even in barter, to the extent that it is somewhat developed as barter, i.e. is a repeated, normal operation, not merely an isolated act of exchange, some other commodity appears as measuring unit, e.g. cattle with Homer. Among the savage Papuans of the coast, who, in order 'to obtain a foreign article, barter 1 or 2 of their children, and if they are not to hand, borrow those of their neighbours, promising to give their own in exchange, when they come to hand, this request being rarely refused', there exists no measure for exchange. The only side of exchange which exists for the Papuan is that he can obtain the alien thing only by dispossessing himself of something he possesses. This dispossession [*Entäusserung*] itself is regulated for him by nothing but his fancy on one side, and the scope of his movable possessions on the other. In the *Economist* of 13 March 1858, we read, in a letter addressed to the editor: 'As the substitution in France of gold for silver in the coinage (which has been the principal means hitherto of absorbing the new discoveries of gold) must be approaching its completion, particularly as less coinage will be wanted for a stagnant trade and reduced prices, we may expect ere long that our fixed price of £3 17s. 10 1/2d. an ounce will attract the gold here.' [45] Now what does this, our 'fixed price of an ounce' of gold, mean? Nothing other than that a certain aliquot part of an ounce is called pence, a certain multiple of this pennyweight of gold a shilling, and a certain multiple of this shilling-weight of gold a pound? Does the gentleman imagine that in other countries the golden Guilder, the Louis d’or etc. do not likewise signify a specific quantity of gold, i.e. that a specific quantity has a fixed name? and that this is an English privilege? or a speciality? That, in England, a monetary coin expressed in gold is more than a monetary coin, and in other countries, less? It would be interesting to know what this noble spirit imagines the exchange rate to be.

What leads Steuart astray is this: the prices of commodities express nothing but the relations in which they are exchangeable for one another, the *proportions* in which they exchange for one another. These proportions given, I can call the unit any name whatever, because the undenominated abstract number would suffice, and instead of saying that this commodity = 6 stivers, the other = 3 etc., I could say this one = 6 ones, the other = 3; I would not have to give the unit any name at all. Since the numerical relation is all that matters at that point, I can give it any name whatever. But it is already presupposed here that these proportions are *given,* that the commodities have previously become commensurable magnitudes. As soon as magnitudes have once been posited as commensurable, their relations become simple numerical relations. Money appears as measure, and a specific quantity of the commodity in which it represents itself appears as measuring unit, precisely in order to find the *proportions,* and to articulate and to handle commodities as commensurable ones. This real unit is the labour time relatively objectified in them. However, it is labour time itself posited as general. The process by which values within the money system are determined by labour time does not belong in the examination of money itself, and falls outside circulation; proceeds behind it as its effective base and presupposition. The question here could only be this: instead of saying this commodity is = to one ounce of gold, why does one not say directly it is = to *x* labour time, objectified in the ounce of gold? Why is labour time, the substance and measure of value, not at the same time the measure of prices, or, in other words, why are price and value different at all? Proudhon’s school believe it a great deed to demand that this identity be posited and that the price of commodities be expressed in labour time. The coincidence of price and value presupposes the equality of demand and supply, exchange solely of equivalents (hence not of capital for labour) etc.; in short, formulated economically, it reveals at once that this demand is the negation of the entire foundation of the relations of production based on exchange value. But if we suppose this basis suspended, then on the other side the problem disappears again, which exists only of it and with it. That the commodity in its unmediated presence as use value is not value, is not the adequate form of value = that it is [the adequate form of value] as an objective other, or that it is this as equated to another object; or, that value possesses its adequate form in a specific object as distinct from another. Commodities, as values, are objectified labour; the adequate value must therefore itself appear in the form of a specific thing, as a specific form of objectified labour.

Steuart illustrates this drivel about an ideal standard with two historic examples, of which the first, the bank money of Amsterdam, shows just the opposite, since it is nothing but the reduction of circulating coins to their bullion content (metal content); the second one has been repeated after him by all the moderns who follow the same tendency. For example, Urquhart cites the example of the Barbary Coast, where an ideal bar, an iron bar, a merely imaginary iron bar, counts as standard which neither rises nor falls. If e.g. the real iron bar falls, say by 100%, then the bar is worth 2 iron bars; if it rises again by 100%, then only one. Mr Urquhart claims to have observed at the same time that the Barbary Coast knows neither commercial nor industrial crises, but least of all monetary crises, and ascribes this to the magical effects of this ideal standard of value. [46] This ‘ideal’ imaginary standard is nothing but an imagined real value; an imagined notion, however, which, because the monetary system has not developed its further determinants – a development depending on quite different relations – achieves no objective reality. It is the same as if, in mythology, one were to consider as the higher religions those whose god-figures are not worked out in visible form but remain stuck in the imagination, i.e. where they obtain at most an oral, but not a graphic presence; The bar rests on a real iron bar, which was later transformed into a fantasy-creature and fixated as such. An ounce of gold, expressed in English accounting money, = £3 17s. 10 1/2d. Well. Well. Say a pound of silk had had exactly this price; but that it had later fallen to where Milanese raw silk stood on 12 March ’58 in London, the lb. at £1 8s. It is the imaginary conception of an amount of iron, an iron bar, which keeps the same value (1) relative to all other commodities, (2) relative to the labour contained in it. This iron bar is of course purely imaginary, but it is not so fixed and 'standing like a rock in the sea' [47] as Steuart, and nearly a 100 years later Urquhart, believes. The only thing fixed in the iron bar is the name; in one case the real iron bar contains 2 ideal ones, in the other, only 1. This is expressed in such a way that the same, unchangeable ideal one is first = 2, then = 1 real bar. Thus, this posited, only the relation of the real iron bar has changed, not the ideal one. But in fact the ideal iron bar is twice as long in one case as in the other, and only its name is unchanged. In one case 100 lb. of iron are called e.g. a bar, in the other, 200 a bar. Suppose money were issued which represented labour time, e.g. time-chits; this time-chit itself could be baptized any name one wished, e.g. one pound, a twentieth of an hour 1s., 1/240th of an hour 1d. Gold and silver, like all other commodities, depending on the production time they cost, would express different multiples or fractional parts of pounds, shillings, pence etc., and an ounce of gold could just as well be = £8 6s. 3d. as £3 17s. 10 1/2d. These numbers would always be the expression of the proportion in which a specific quantity of labour is contained in the ounce. Instead of saying that £3 17s. 10 1/2d. = one ounce of gold, now cost only 1/2 lb. of silk, one can imagine that the ounce is now = £7 15s. 9d. or that £3 17s. 10 1/2d. are now only equal to half an ounce, because they are now only half the value. If we compare prices in England in e.g. the fifteenth century with those of the eighteenth, then we may find that two commodities had e.g. entirely the same nominal money value, e.g. 1 pound sterling. In this case the pound sterling is the standard, but expresses four or five times as much value in the first case as in the second, and we could say that, if the value of this commodity is = 1 ounce in the fifteenth century, then it was = 1/4 ounce of gold in the eighteenth; because in the eighteenth, 1 ounce of gold expresses the same labour time as 1/4 ounce in the fifteenth century. It could be said, therefore, that the measure, the pound, had remained the same, but in one case = four times as much gold as in the other. This is the *ideal standard.* The comparison we make here could have been made by the people of the fifteenth century themselves, if they had lived on into the eighteenth; they would say that 1 ounce of gold, which is now worth £1, was only worth 1/4 before. 4 pounds of gold now worth no more than 1 in the fifteenth century. If this pound previously had the name of *livre,* then I can imagine that one *livre* had been = 4 pounds at that time, and is now = to only 1; the value of gold had changed but that the standard, the *livre,* had remained the same. In fact, one *livre* in France and England originally meant 1 pound of silver, and now only 1/*x*. It can be said, therefore, that the name, *livre,* the standard, had remained nominally the same always, but that silver had changed its value in comparison to it. A Frenchman who had lived from the time of Charlemagne until today could say that the *livre* of silver had always remained the standard of value, unchanged; it had once been worth 1 pound of silver, but, owing to a variety of misfortunes, had finished up being worth only 1/*x* of a pennyweight. The ell is the same; only its length is different in different countries. It is in fact the same as if the product of one working day, the gold brought to light in one day of work, were given the name *livre;* this *livre* would always remain the same, although it would express very different amounts of gold in different periods.

What do we do in fact when we compare £1 of the fifteenth century with £1 of the eighteenth? Both are the same mass of metal (each = 20s.), but of a different value; since the metal was then worth 4 times as much as now. We say therefore that, compared with today, the *livre* was = 4 times the mass of metal it contains today. And one could imagine that the *livre* had remained unchanged, but had been = 4 real *livres* of gold then, only = 1 today. The matter would be correctly comparable not in regard to the quantity of metal contained in a *livre,* but rather in regard to its value; this value, however, in turn expresses itself quantitatively in such a way that 1/4 *livre* gold, then, = 1 *livre* gold today. Well; the *livre* identical, but at that time = 4 real *livres* of gold (by today's value) and now only = 1. If gold falls in value, and its relative fall or rise as regards other articles is expressed in their price, then, instead of saying that an object which cost £1 of gold before now costs 2, it could be said that it still costs 1 pound, but 1 pound is now worth 2 real *livres* of gold etc.; i.e. 1 *livre* of 2 real gold *livres* etc. Instead of saying: I sold this commodity yesterday at £1, today I sell it at £4, I might say that I sell it at £1, but yesterday at 1 pound of 1 real pound, today at 1 pound of 4 real pounds. The remaining prices all follow by themselves as soon as the relation of the real bar to the imaginary one is established; but this simply the comparison between the past value of the bar and its present one. The same as if we calculated everything in the £ of the fifteenth century for instance. This Berber or Negro does the same thing that every historian must do who pursues one kind of coin, one accounting name for a coin of the same metallic content, from one century to the next; if he computes it in contemporary money, he must equate it to more or less gold depending on its changing value in different centuries. [49] It is semi-civilized man's effort to establish an unchanging value for the unit of money, for the mass of metal which counts as measure; to fix this value, also, as a constant measure. But at the same time, the cleverness to know that the bar has changed its real value. With the small number of commodities which this Berber has to measure, and with the vigour of tradition among the uncivilized, this complicated method of calculating is not as difficult as it looks.

1 ounce is = £3 17s. 10 1/2d., i.e. not quite = £4. But for convenience's sake let us assume it to be exactly = £4. Then 1/4 of an ounce of gold therefore obtains the name pound, and serves under this name as accounting coin. But this pound changes its value, partly relative to the value of other commodities which change their value, partly in so far as it is itself the product of more or less labour time. The only firm thing about it is the name, and the quantity, the fractional part of the ounce, of the weight-unit of gold, whose baptismal name it is; which is contained, thus, in one piece of money, called one pound.

The savage wants to hold it constant as unchangeable value, and thus the quantity of metal it contains changes for him. If the value of gold falls by 100%, then the pound is the measure of value for him as before; but a pound of 2/4 ounces of gold etc. The pound for him always equals a mass of gold (iron) which has the same value. But since this value changes, it sometimes equals a greater, sometimes a smaller quantity of real gold or iron, depending on whether more or less of them must be given in exchange for other commodities. He compares the contemporary value with the past value, which latter counts as standard for him, and survives only in his imagination. Thus, instead of calculating in 1/4 ounce of gold, whose value changes, he calculates in the value which 1/4 ounce of gold previously had, hence in an imaginary unchanged 1/4 ounce-value, which expresses itself, however, in varying quantities. On one side the effort to establish a fixed value for the value-standard; on the other side, the cleverness of nevertheless avoiding trouble by making a detour. But it is altogether absurd to take this accidental displacement, this way in which semi-savages have assimilated the measurement of values in money, forced on them from the outside, by first displacing it and then getting themselves straight again in the displacement, and to regard this as an organic historical form, or even to erect it as a higher form compared to more developed relations. These savages also take a quantity, the iron bar, as point of departure; but they hold fast to the value which this traditionally had, as accounting unit etc.

This question achieved significance in the modern economy chiefly owing to two circumstances: (1) It has been experienced at various times, e.g. in England during the Revolutionary War [50] that the price of raw gold rose above the price of minted gold. This historic phenomenon thus seemed irrefutably to prove that the names which are given to certain fractional weight-parts of gold (precious metal), pound, shilling, pence etc., by some inexplicable process act in an independent way towards the substance of which they are the name. How else could an ounce of gold be worth more than the same ounce of gold minted in £3 17s. 10 1/2d.? Or how could an ounce of gold be worth more than 4 *livres* of gold, if *livre* is merely the name for 1/4 ounce? On closer inspection it was found, however, that the coins which circulated under the name pound in fact no longer contained the normal metallic content, so that, for instance, 5 circulating pounds in fact weighed only 1 ounce of gold (of the same refinement). Since a coin which allegedly represented 1/4 ounce of gold (thereabouts) in fact represented only 1/5, it was very simple that the ounce = 5 of this kind of circulating £; hence that the value of the bullion price rose above the mint price, in that in fact no longer 1/4 but merely 1/5 of an ounce of gold was called pound, represented money, had that name; was merely the name, now, for 1/5 of an ounce. The same phenomenon took place when, although the metal content of the circulating coins had not fallen below their normal measure, they circulated at the same time as depreciated paper money, while to melt them down and to export them was prohibited. In that case, the 1/4 ounce of gold circulating in the form of £ shared in the depreciation of the notes; a fate from which gold in bars was exempt. * The fact was again the same; the accounting name, pound, had ceased to be the name for 1/4 ounce, became the name for a lesser amount. Thus the ounce equalled e.g. 5 of such pounds. This means, then, that the bullion price rose above the mint price. These or analogous historical phenomena, all capable of equally simple solution and all belonging to the same series, led therefore to the notion of the *ideal measure,* or, that money as measure was only a point of comparison, not a specific quantity. Hundreds of volumes have been written about this case in England in the past 150 years.

* The mint price can also be raised above the bullion price within a country by the mintage.

That a specific sort of coin should rise above its bullion content is not in itself something strange, since new labour (to give it form) is added to the coin. But regardless of that, it happens that the value of a specific sort of coin rises above its bullion content. This is of no economic interest whatever, and has as yet led to no economic studies. It means nothing more than that, for certain purposes, gold and silver was requisite in precisely this form, say of British pounds or of Spanish dollars. The directors of the Bank had, of course, a particular interest in proving that the value of notes had not fallen, but rather that of gold had risen. As to the last question, this can be treated only later.

(2) But the theory of the *ideal measure* was first brought up at the beginning of the eighteenth century and again in the second decade of the nineteenth, where questions were at issue in which money figures not as measure, nor as medium of exchange, but rather as constantly self-identical equivalent, as value for-itself (in the third aspect) and hence as the universal material of contracts. The issue both times was whether or not debts of state, and other debts, contracted in a depreciated money, should be acknowledged and paid back in full-valued money. It was a question simply between the creditors of the state and the mass of the nation. This question itself does not concern us here. Those who demanded a readjustment of claims on the one side, and of payments (obligations) on the other, chose the wrong battlefield in asking whether or not the *standard of money* ought to be changed. On this occasion, then, crude theories of this type were brought forward about the standard of money, fixing of the price of money, etc. ('Altering the standard like altering the national measures or weights.' Steuart. It is clear at the first glance that the mass of grain in a nation does not change by the unit measure of e.g. the bushel being doubled or halved. But the change would be very important for e.g. farmers who had to pay grain rent in a specific number of bushels, if, were

the measure doubled, they then had to supply the same number of bushels as before.) In this case, it was the creditors of the state who clung to the name ‘pound’, regardless of the fractional weight-unit of gold which it expressed, i.e. to the ‘ideal standard’ – for the latter is in fact only the accounting name for the weight-unit of metal which serves as measure. Strangely enough, however, it was precisely their opponents who advanced this theory of the ‘ideal standard’, and they themselves who combated it. Instead of simply demanding a readjustment, or that the creditors of the state ought to be paid back only the amount, in gold, which they had in fact advanced, they demanded that the standard be reduced in accordance with depreciation; thus e.g. if the pound sterling had fallen to 1/5 of an ounce of gold, that this 1/5 ounce should henceforth carry the name pound, or that the pound ought perhaps to be minted in 21 shillings instead of in 20. This reduction of the *standard* was called raising the value of money; in that the ounce now = £5 instead of = 4 as previously. Thus, they did not say that those who had advanced e.g. 1 ounce of gold in 5 depreciated pounds now ought to get 4 full-valued pounds back; they said, rather, that they should be repaid 5 pounds, but that the pound ought henceforth to express 1/20 of an ounce less than before. When they raised this demand in England after the resumption of cash-payment, the accounting coin had regained its old metal value. On this occasion yet further crude theories about money as the measure of value were constructed, and, on the pretense of refuting these theories, whose falsity was simple to prove, the interests of the creditors of the state were smuggled through. The first battle of this sort between Locke and Lowndes. From 1688 to 1695 the state contracted debts in depreciated money – depreciated owing to all full-weighted money having been melted down, and only the light-weight being in circulation. The guinea had risen to 30s. Lowndes (mintmaster?) (secretary to the treasury) wanted to have the £ reduced by 20%; Locke stood by the old standard of Elizabeth. In 1695 the general recoinage. Locke won the day. Debts contracted at 10 and 14s. the guinea, paid back at the rate of 20s. This equally advantageous for the state and for the landed proprietors. ‘Lowndes posed the question on the wrong basis. First he asserted that his scheme was not a debasement of the old standard. Then he ascribed the rise of the bullion price to the inherent value of silver and not to the lightness of the coin with which it was bought. He always supposed that it was the stamp and not the substance which made the currency … For his part, Locke only asked himself whether or not Lowndes's scheme included a debasement, but never inquired into the interests of those who are engaged by permanent contracts. Mr Lowndes's great argument for reducing the standard was that silver bullion was risen to 6s. 5d. per ounce (i.e. that it might have been bought with 77 pence of shillings of 1/77 part of a pound troy) and was therefore of the opinion that the pound troy should be coined into 77s., which was a diminution of the value of the £ by 20% or 1/5. Locke replied to him that the 77s. were paid in clipped money and that they were not more than 62 pence standard coin, by weight … But ought a man who had borrowed £1,000 in this clipped money to be obliged to pay back £1,000 in standard weight? Both Lowndes and Locke developed only quite superficially the influence of a change of standard on the relation of debtors and creditors, … the credit system then still little developed in England … the landed interest and the interest of the crown, were only attended to. Trade at that time was almost at a stop, and had been raised at a piratical war … Restoring the standard was the most favourable, both for the landed interest and the exchequer; and so it was gone in for.' (Steuart loc. cit. Vol. II. p. 178, 179.) Steuart ironically remarks on the whole transaction: 'By this raising of the standard the government gained significantly as regards taxes, and creditors on their capital and interest; and the nation, which was the principal loser, was satisfied (pleased) (quite joyful) because *its* standard' (i.e. the measure of its own value) 'was not debased; so were all the three parties satisfied.' (loc. cit. Vol. II, p. 156.) Compare John Locke. *Works.* 4 vols. 7th ed., London, 1768; as well as the essay 'Some Considerations on the Lowering of Interest and Raising the Value of Money' (1691); and also: 'Further Considerations Concerning Raising the Value of Money, wherein Mr Lowndes's arguments for it, in his late Report concerning "An Essay for the amendment of the silver coins", are particularly examined', both in Vol. II. In the first monograph it says, among other things:

'The *raising of money,* about which so much nonsense is now being uttered, is either *raising value of our money,* and that you cannot do; or *raising the denomination of our coin.'* (p. 53.) 'For example, term a crown what previously was called 1/2 a crown. The value remains determined by the metal content. If the abating 1/20 of the quantity of the silver of any coin, does not lessen its value, the abating 19/20 of the quantity of the silver of any coin, will not abate its value. Thus, according to this theory, a single three pence or a single farthing, being called a crown, will buy as much spice or silk, or any other commodity, as a crown-piece which contains 20 or 60 times as much silver.' (p. 54.) 'The raising of money is thus nothing but giving a less quantity of silver the stamp and denomination of a greater.' (loc. cit.) 'The stamp of the coin a guarantee to the public; it must contain so much silver under such a denomination.' (57.) 'It is silver, and not names, that pays debts and purchases commodities.' (p. 58.) 'The mint stamp suffices as guarantee for the weight and the fineness of the piece of money, but lets the thus-coined gold money, find its own rate, like other commodities.' (p. 66.) In general one can do nothing with the raising of money but make 'more money in tale', but not more 'money in weight and worth'. (p. 73.) 'Silver is altogether a different standard from the others. The ell or the quart with which people measure may remain in the hands of the seller, of the buyer or of a third person: it matters not whose it is. But silver is not only the measure of bargains, it is the thing bargained for, and passes in trade from the buyer to the seller, as being in such a quantity equivalent to the thing sold: and so it not only *reassumes* the value of the commodity it is applied to, but is given in exchange for it, as of equal value. But this it does only by its quantity, and nothing else.' (p. 92.) 'The raising being but giving of names at pleasure to aliquot parts of any piece, viz. that now the sixtieth part of an ounce still be called a penny, may be done with what increase you please.' (118.) 'The privilege that bullion has, to be exported freely, will give it a little advance above our coin, let the denomination of that be raised, or fall as you please, whilst there is need of its exportation, and the exportation of our coin is prohibited by law.' (p. 119, 120.)

The same position adopted by Lowndes against Locke, in that the former believed the rise of the bullion price to be due to a rise in the value of bullion, as a result of which the value of the accounting coin had declined (i.e. because the value of bullion rose, the value of a fractional part of it, called £, fell), was adopted by the little-shilling-men – Attwood and the others of the Birmingham school 1819 seq. (Cobbett had posed the question on the correct ground: non-adjustments of national debts, rents etc.; but spoiled it all by his false theory which condemned paper money as such. [51] (Strangely enough, he came to this conclusion by beginning, like Ricardo, who comes to the opposite conclusion, from the same false premise, the determination of price by the quantity of the medium of circulation).) Their entire wisdom in the following phrases: ‘In his dispute with the Birmingham Chamber of Commerce, Sir R. Peel asks: “What will *your* pound note represent”’ (p. 266. ‘The Currency Question’, *The Gemini Letters,* London, 1844) (namely, the pound note if not paid in gold). ‘Now what is meant by the present standard of value? … £3 17s. 10 1/2d., do they signify one *ounce of gold* or its *value?* If the ounce itself, why not call things by their names and say, instead of pound, shilling, pence, ounces, pennyweights and grains? Then we go back to a *direct system of barter.’* (p. 269. Not quite. But what would Mr Attwood have gained if people said ounce instead of £3 17s. 10 1/2d., and so many pennyweight instead of shillings? That, for convenience in calculating, the fractional parts are given names – which apart from that, also indicates that the metal is here given a social quality alien to itself – what witness does it bear either for or against Attwood’s doctrine?) ‘Or the *value?* If an ounce = £3 17s. 10 1/2d., why at different periods money £5 4s., and then again 3,17, 9? … the expression pound has reference to *value,* but not *a fixed standard value … Labour* is the parent of cost, and gives the relative value to gold or iron.’ (And that is in fact why the value of one ounce and of £3 17s. 10 1/2d. changes.) ‘*Whatever denomination or words are used to express the daily or weekly labour of a man,* such words express the cost of commodity produced.’ (p. 270.) The word ‘one pound is the *ideal* unit’. (p. 272.) The last sentence important because it shows how this doctrine of the ‘ideal unit’ dissolves into the demand for a money which is supposed directly to represent labour. Pound then e.g. the expression for 12 days’ work. The demand is this, that the determination of value should not lead to that of money as a distinct quantity, or that labour as the measure of values should not compel the labour objectified in a specific commodity to be made the measure of the other values. The important thing is that this demand is here made from the standpoint of the bourgeois economy (thus also by Gray, who actually works out this matter to perfection, and of whom we will speak in a moment), not from the standpoint of the negation of the bourgeois economy, as e.g. with Bray. The Proudhonists (see e.g. Mr Darimon) have indeed succeeded in raising this demand both as one corresponding to the present relations of production and also as a demand which totally revolutionizes them, and a great innovation, since, as *crapauds*, [52] they are of course not required to know anything of what has been written or thought on the other side of the Channel. At all events, already the simple fact that this demand was raised more than 50 years ago in England by a fraction of bourgeois economists shows to what extent the socialists who pretend thereby to advance something new and anti-bourgeois are on the wrong track. About the demand itself, see above. (Only a few things from Gray can be added here. As to the rest, the matter can be gone into in detail only in the banking system.)

[More on the critique of theories about medium of circulation and money. – *Transformation of the medium of circulation into money. – Formation of treasures. – Means of payment. – Prices of commodities and quantity of circulating money. – Value of money*]

As regards money as constantly self-identical equivalent, i.e. as *value* as such, and thus as the material of all contracts, it is clear that the changes in the value of the material in which it represents itself (directly, as in gold, silver, or indirectly, as claims, in notes, on specific quantity of gold, silver etc.) must bring about great revolutions between the different classes of a state. This not to be examined here, since these relations presuppose knowledge of the various economic relations. Only something by way of illustration. In the sixteenth and seventeenth centuries, it is well known that the depreciation of gold and silver, due to the discovery of America, depreciated the labouring class and that of the landed proprietors; raised that of the capitalists (specially of the industrial capitalists). In the Roman republic, the appreciation of copper turned the plebeians into the slaves of the patricians. 'Since one was forced to pay the largest sums in copper, one had to hold this money in masses or in stamped fragments which were tendered and received by weight. Copper in this state was *aes grave.* Metal money weighed. [53] <Originally copper without stamp among the Romans; then stamping of external coins. *Servius rex ovium boumque effigie primus aes signavit.* [54] (Pliny, *Historia naturalis* I. 18, c. 3.)> After the patricians had stockpiled a mass of this dark and ugly metal … they tried to free themselves from it, either by buying from the plebeians all the land which the latter would sell, or by lending at long term. This value had cost them nothing to acquire, and was a hindrance to them, so they were forced to rid themselves of it unsparingly. The competition of all who had the same desire of getting rid of it necessarily brought about, in a short time, a considerable reduction of the price of copper in Rome. At the beginning of the fourth century after the foundation of Rome, as one may see from the Lex Menenia (302 A.U.C.), the relation of copper to silver = 1:960 … This metal, so depreciated in Rome, at the same time one of the most sought-after articles of trade (since the

Greeks made their works of art out of bronze etc.) ... The precious metals came to be exchanged in Rome for copper, with enormous profits, and so lucrative a commerce stimulated new imports each day ... Little by little the patricians exchanged their treasure for ingots of gold and of silver, *aurum infectum, argentum infectum,* [55] in place of these piles of old copper, so troublesome to dispose of and so disagreeable to look at. After the defeat of Pyrrhus and particularly after the conquests in Asia ... the *aes grave* had already quite vanished, and the requirements of circulation had necessitated the introduction of the Greek victoria, and the name *victoriatus ...* of a weight of 1 1/2 scruples of silver, like the Attic coin, the drachma; in the *seventh century* A.U.C. the lex Clodia made Roman coin of it. It was usually exchanged for the pound of copper or the *as of 12 ounces.* Thus between silver and copper the relation of 192:1, i.e. a 5 times weaker relation than during the time of the greatest depreciation of copper due to export; still, copper cheaper in Rome than in Greece and Asia. This great revolution in the exchange value of the monetary substance, to the measure it proceeded, most cruelly worsened the lot of the unfortunate plebeians, who had obtained the depreciated copper as a loan, and, having spent or used it at the rate it then had, now owed, by the letter of their contracts, a five times greater sum than they had borrowed in reality. They had no means to buy their way out of servitude ... Whoever had borrowed 3,000 *as* during the time when this sum = 300 oxen or 900 *scruples* of silver, could then obtain these only for 4,500 *scruples* of silver, when the *as* was represented by 1 1/2 *scruples* of this metal ... If the plebeian gave back 1/5 of the copper he had obtained, then he had in reality paid off his debt, for 1/5 now the same value as 1 at the time the contract was made. Copper had risen 5 times in value compared to silver ... The plebeians demanded a revision of the debt, a new appraisal of the sum due, and a change in the title of their original obligation ... While the creditors did not demand the restitution of the capital, the payment of interest was itself unbearable, because the interest, originally stipulated as 12%, had, owing to the excessive rise in cost of the specie, become as onerous as if it had been fixed at 60% of the principal. By way of concession, the debtors obtained a law that deducted the accumulated interest from the capital ... The senators resisted letting go of the means by which they held the people in the most abject dependence. The masters of nearly all landed property, armed with legal titles which authorized them to throw their debtors into irons and to sentence them to corporal punishment, suppressed the uprisings and persecuted the most mutinous. Every patrician's home was a prison. Finally wars were got up which gave the debtor some payment, with a suspension of obligations, and which opened to the creditor new sources of wealth and of power. This the internal situation in Rome at the time of the defeat of Pyrrhus, the capture of Taranto and important victories over the Samnians, Lucanians and other South-Italian peoples etc. ... 483 or 485 the first Roman silver coin, the *libella; ...* was called *libella* because of small weight = *libra* of 12 ounces of copper.' (Garnier, Germain, *Histoire de la Monnaie* etc., 2 vols., Paris, 1819. Vol. II. p. 14–24.)

<Assignats. 'National Property. Assignat of 100 *frs.'* legal tender ... They are distinguished from all other notes in not *even professing to represent any specified thing.* The words 'national property' meant that their value could be obtained by buying confiscated properties with them at the continuous auctions of the latter. But no reason why this value called 100 fr. It depended on the comparative quality of the property so purchasable and the number of assignats issued.' (78, 79, Nassau W. Senior, *'Three Lectures on the Cost of Obtaining Money'* etc., London, 1830.)

'The *livre de compte,* introduced by Charlemagne, almost never represented by a real equivalent coin, retained its name, as well as its divisions into *sous* and *deniers,* until the end of the eighteenth century, while real coins have varied infinitely in form, size, value, not only with every change of government, but even under the same reign. The value of the *livre de compte* nevertheless underwent enormous diminutions ... but this always an act of force.' (p. 76, Vol. I. Garnier, loc. cit.) All coins in antiquity originally weights. (loc. cit. p. 125.)

'Money is in the first place the universally marketable commodity, or that in which every one deals for the purpose of procuring other commodities.' (Bailey: *'Money and its Vicissitudes'* etc., London, 1837, p. 1.) 'It is the great *medial* commodity.' (loc. cit. p. 2.) It is the *general commodity of contracts,* or that in which the majority of bargains about property, to be completed at a future time, are made. (p. 3.) Finally, it is the *'measure of value ...* Now, as all articles are exchanged for money, the mutual values of A and B are necessarily shown by their values in money or their prices … as the comparative weight of substances are seen by their weight in relation to water, or their specific gravities.’ (p. 4.) ‘The first essential requisite is that money should be uniform in its physical qualities, so that equal quantities should be so far identical as to present no ground for preferring one to the other … For example, grain and cattle already for this reason not useful, because an equal quantity of grain and equal numbers of cattle are not always alike in the qualities for which they are preferred.’ (p. 5, 6.) ‘The *steadiness of value* is so desirable in money as medial commodity and a commodity of contract; it is quite unessential to it in its capacity of the measure of value.’ (p. 9.) ‘Money may continually vary in value, and yet be as good a measure of value as if it remained perfectly stationary. Suppose e.g., it is reduced in value and the reduction in value implies a reduction of value in relation to some one or more commodities, suppose it is reduced in value in relation to corn and labour. Before the reduction, a guinea would purchase three bushels of wheat, or six days’ labour; subsequently, it would purchase only two bushels of wheat or four days’ labour. In both cases, the relations of wheat and labour to money being given, their mutual relations can be inferred; in other words, we can ascertain that a bushel of wheat is worth two days’ labour. This, which is all that measuring value implies, is as readily done after the reduction as before. The excellence of any thing as a measure of value is altogether independent of its own variableness in value … One confuses invariableness of value with invariableness in fineness and weight … The command of *quantity* being that which constitutes value, a *definite quantity* of a substance of some uniform commodity must be used as a unit to measure value; and it is this definite *quantity* of a substance of uniform quality which must be invariable.’ (p. 11.) In all money contracts the issue at stake is the *quantity* of the gold and silver to be lent, not its value. (p. 103.) ‘If someone were to insist that it be a contract for a specified *value,* he is bound to show in relation to what commodity: thus, he would be maintaining that a pecuniary contract does not relate to a quantity of money as expressed on the face of it, but to a quantity of some commodity of which no mention is made.’ (p. 104.) ‘It is not necessary to restrict this to contracts where actual *money* is lent. It holds for all obligations for the future payment of money, whether for articles of any kind sold on credit, or for services, or as rent of land or houses; they are precisely in the same condition as pure loans of the medial commodity. If A sells a ton of iron to B for ten pounds, at twelve months' credit, it is just the same in effect as lending the ten pounds for a year and the intents of both contracting parties will in the same way be affected by changes in currency.' (p. 110, 111.)

The confusion of giving names to specified and unchangeable fractional parts of the money substance which is to serve as unit of measure – confusing the denomination of it with fixing the *price* of money – is also displayed, among others, by the high-flown romanticist of political economy, Mr Adam Müller. He says, among other things: 'Every one can see how much depends on the true *determination* of the *mint price,* above all in a country like England, where the government, with generous liberality' (i.e. at the country's expense and the profit of the Bank of England bullion dealers) 'mints without charge, collects no mintage etc., and thus, if it set the mint price significantly higher than the market price, if, instead of paying an ounce of gold at £3 17s. 10 1/2d., as now, it set £3 19s. as the mint price of one ounce of gold, then all gold would flow towards the mint, all the silver there would be changed into the cheap gold here, and thus be brought to the mint anew, and the currency system would become disordered.' (p. 280, 281, Vol. II. *Die Elemente der Staatskunst,* Berlin, 1809.) Herr Müller does not know, then, that pence and shillings here are only names for fractional parts of a gold ounce. Because silver and copper coins – which, notabene, are not minted according to the proportion of silver and copper to gold, but are issued as markers for the equivalent parts of gold, and hence need be accepted in payment only in very small amounts – circulate under the names of shillings and pence, he imagines that an ounce of gold is divided into pieces of gold, of silver, and of copper (thus triple standard of value). A couple of steps later he suddenly remembers again that there is no double standard in England, hence even less a triple one. Herr Müller's lack of clarity about the 'common' economic relations is the real foundation of his 'higher' conception.

From the general law that the total price of commodities in circulation determines the mass of the circulating medium at a given stage of the velocity of circulation, it follows that at a given stage of growth of the values thrown into circulation, the more precious metal – the metal of greater specific value, i.e. which contains more labour time in a smaller amount – takes the place of the less precious as the predominant medium of circulation; hence, copper, silver, gold, each one replacing the previous one as the predominant medium of circulation. The same aggregate sum of prices can be circulated e.g. with 14 times as few gold coins as silver coins. Copper or even iron coin as predominant medium of circulation supposes weak circulation. Just as the more powerful but more valuable means of transport and means of circulation takes the place of the less valuable to the degree that the mass of circulating commodities, and circulation generally, grows.

On the other side it is clear that the small retail traffic of everyday life requires exchange on a very diminutive scale – the smaller, the poorer the country and the weaker is circulation as such. It is in this retail traffic, where very small amounts of commodities on the one side, hence also very small values circulate, that money appears in the most proper sense of the word merely as vanishing medium of circulation, and does not congeal as realized price. Consequently, a subsidiary medium of circulation enters for this traffic, which is merely the symbol of the fractional parts of the predominant media of circulation. These are silver and copper markers, which are therefore not minted in the relation of the value of their substance to the value of e.g. gold. Here money appears still only as symbol, even if itself still in a relatively valuable substance. Gold e.g. would have to be divided into excessively small fractions to serve as equivalent of the division of commodities required by this retail traffic.

This is why these subsidiary media of circulation need be accepted in payment, by law, in only very small amounts, so that they can never solidify as realization of price. For example, in England, copper in the amount of 6d., silver in the amount of 20s. The more developed circulation is generally, the greater the mass of prices of the commodities entering into circulation, the more does their wholesale exchange separate off from their retail exchange, and they require different sorts of coin for their circulation. The velocity of the circulation of these markers is inversely related to the magnitude of their value.

‘In the early stage of society, when nations are poor, and their payments trifling, copper has frequently been known to answer all the purposes of currency and it is coined into pieces of very low denominations in order to facilitate the inconsiderable exchanges which then take place. So in the early age of the Roman Republic and of Scotland.' (p. 3.) (David Buchanan, '*Observations on the Subjects, treated of in Dr Smith's Inquiry*' etc., Edinburgh, 1814.) 'The general wealth of a country is very accurately measured by the nature of its payments and the state of its coin; and the decided prevalence of a coarse metal in its currency, joined to the use of coins of very low denomination, marks a rude state of society.' (p. 4.) Later 'the business of currency becomes divided into two distinct departments; the duty of effecting the main payments … for the more precious metals; the inferior metals by contrast retained for some trivial exchanges, and thus purely subservient to the main currency. Between the first introduction of a precious metal into the currency of a country, and its exclusive use in the main payments, a wide interval; and the payments of the retail trade must in the interval have become so considerable, owing to the increase of wealth, that at least in part they could be conveniently managed by the new and more valuable coin; since no coin can be used for the main payments' (this is false, as the notes show) 'which is not suited, at the same time, to the transactions of the retail trade, since every trade ultimately obtains from the consumer … the return of its capital … Silver has maintained itself everywhere on the continent in the main payments … In Britain the quantity of silver in circulation does not exceed what is necessary for the smaller payments … in fact few payments to the amount of 20s. made in silver … Before the reign of William III silver was brought in large bags to the treasury in payment of the national revenue. At this period the great change took place … The exclusive introduction of gold in the main payments of England was a clear proof that the *returns of the retail trade at this time were made mainly in gold;* this possible without a single payment ever exceeding or even equalling any of the gold coins; because, in the general abundance of gold, and scarcity of silver, gold coins naturally offered for small sums and a balance of silver demanded in return; so that gold, by thus assisting in the retail trade and in economizing the use of silver, even for the small payments, would prevent its *accumulation* by the retail trader … At the same time, as in England gold was substituted for silver' (1695) 'for the main payments, silver for copper in Sweden … *Clear, that the coin used for the larger payments can only pass current at its intrinsic worth …* But intrinsic worth *not necessary for a subsidiary currency …* In Rome, so long as copper the prevailing coin, current only for its intrinsic value … 5 years before the beginning of the first Punic war, silver introduced, little by little displaced copper in the main payments … 62 years after the silver, gold, but it never seems to have excluded silver from the main payments … In India, copper not a subsidiary currency; passes therefore for its intrinsic worth. The rupee, a silver coin of 2s. 3d., is the money of account; in relation to which the mohour, a gold coin, and the pice, a copper coin, are allowed to find their value in the market; the number of pice currently exchanged for a rupee constantly varies with the weight and value of the coin, while here 24 halfpence always = 1s. without reference to their weight. In India the retail dealer must still take considerable quantities of copper for his goods, and he cannot afford to take it therefore but for its intrinsic value … In the currencies of Europe, copper passes for whatever value is fixed upon it, without examination of its weight and fineness.' (p. 4–18.) In England 'an excess of copper spent 1798 by private traders; and although copper only legal payment for 6d., found its way (the surplus) to the retail traders; they sought to put it in circulation again; but ultimately returned to them. When this currency was stopped, copper accumulated with the retail traders in sums of £20, £30, even £50, which they finally had to sell at their intrinsic value.' (p. 31.)

In the subsidiary currency, the medium of circulation takes on a particular form as such, as a merely vanishing medium, alongside the medium of circulation which is at the same time equivalent, which realizes prices, and accumulates as independent value. Thus, here, pure symbol. Thus it may be issued only in the quantity absolutely required for the small retail trade, so that it can never thereby accumulate. The quantity must be determined by the mass of prices which it circulates, divided by its velocity. Because the mass of the circulating medium, of a certain value, is determined by prices, it follows automatically that if a greater quantity than required by circulation itself were artificially thrown into it and could not run off (which is not the case here, because, as medium of circulation, it is above its intrinsic worth), then it would be depreciated; not because the quantity determines prices, but because prices determine the quantity, and hence only a specific amount can remain in circulation at a specific value. Thus, if there are no openings by which circulation can throw out the superfluous quantity, if the circulating medium cannot change from that form into the form of value for itself, then the value of the medium of circulation must fall. But this can only take place, apart from artificial hindrances, prohibition of melting-down, of export etc., if the circulating medium is merely a symbol, and does not itself possess a real value corresponding to its nominal value, hence cannot make the transition from the form of circulating medium into that of the commodity in general, and shed its stamp; if it is imprisoned in its existence as coin. It follows on the other side that the symbol, the money marker, can circulate at the nominal value of the gold it represents – without possessing any value whatever of its own – in so far as it represents the medium of circulation only in that quantity in which it would itself circulate. But then [it becomes] at the same time a condition either that it is itself then on hand only in such a small quantity that it circulates only in the subsidiary form, hence does not cease for an instant to be a medium of circulation (where it constantly serves partly in the exchange with small amounts of commodities, partly merely to make exchange for the real medium of circulation), hence can never accumulate; or it must possess no value whatever, so that its nominal value can never be compared with its intrinsic value. In the latter case it is posited as mere *symbol,* which, by means of itself, points to value as something existing outside itself. In the other case it never comes to a comparison between its intrinsic value and its nominal value.

Which is why counterfeits of money show an effect immediately; while total destruction of its value does not damage it. It might otherwise appear paradoxical that money can be replaced by worthless paper; but that the slightest alloying of its metallic content depreciates it.

The double function of money in circulation contradicts itself as such; to serve as mere medium of circulation, where it is a vanishing mediation; and at the same time as realization of prices, in which form it accumulates and turns into its third character as money. As medium of circulation it is worn out; thus does not contain the metal content which makes it into objectified labour in a fixed amount. Its correspondence to its value hence always more or less illusory. One example to be presented. It is important to bring in the determination of quantity already at this point in the chapter on money, but deduced in just the opposite way to the usual doctrine. Money can be replaced because its quantity is determined by the prices it circulates. In so far as it, itself, has value – as in the subsidiary medium of circulation – its quantity must be so determined that it can never accumulate as an equivalent, and in fact always figures as an auxiliary cog of the medium of circulation proper. In so far, however, as it is to replace the latter, it must have no value whatsoever, i.e. its value must exist apart from itself. The variations in circulation determined by the amount and number of transactions. (*Economist.*) Circulation may rise, prices remaining equal, by increase in the amount of commodities; if the amount remains constant, by increase of their prices; by both together.

With the proposition that prices regulate the quantity of currency and not the quantity of currency prices, or in other words that trade regulates currency (the quantity of the medium of circulation), and currency does not regulate trade, [it] is, of course, as our deduction has shown, supposed that price is only value translated into another language. Value, and value determined by labour time, is the presupposition. It is clear, therefore, that this law is not equally applicable to the fluctuations of prices in all epochs; e.g. in antiquity, e.g. in Rome, where the circulating medium does not itself arise from circulation, from exchange, but from pillage, plunder etc.

‘No country may consequently have more than one standard; more than one standard for the *measure of value;* for this standard must be uniform and unchanging. No article has a uniform and unchanging value relative to others: it only has such with itself. A piece of gold is constantly of the same value as the other, of exactly the same fineness, the same weight and in the same place; but this cannot be said of gold *and* any other article, e.g. silver.’ (*Econ.* Vol. I p. 771.) [56] *‘Pound* is nothing but a denomination in account, which has reference to a given and fixed quantity of gold of standard quality.’ (loc. cit.) ‘To speak of making one ounce of gold worth £5 instead of £3 17s. 10 1/2d. is to say only that it ought henceforth to be minted in 5 sovereigns instead of in 3 420/480 sovereigns. We would not thereby alter the *value of the gold,* but only the *weight* and hence the *value of* the *pound* or *sovereign.* An ounce of gold would have the same value relative to wheat and all other commodities as before, but since a pound, although bearing the same name as before, would represent a smaller part of an ounce of gold, it would represent a correspondingly smaller quantity of wheat and other commodities. Just as if we had said that a *quarter of wheat* should *no longer be divided into 8, but* *rather into 12 bushels;* we could not thereby change the value of wheat, but merely diminish the quantity contained in a bushel, and hence the latter's value.' (p. 772 loc. cit.) 'Whatever temporary or permanent change might take place, its *price* is always expressed in the same amount of money; an ounce of gold will remain £3 17s. 10 1/2d. of our money. The change in its value indicated by the greater or lesser quantity of the commodities it can purchase.' (loc. cit. p. 890.) [57]

The ideal bar to be compared e.g. with the *ideal milrea* in Buenos Aires (likewise the pound in England during the depreciation of notes etc.). What is fixed here is the name *milrea;* what fluctuates is the quantity of gold or silver it expresses. In Buenos Aires the currency is inconvertible paper money (paper dollars); these dollars originally = 4s. 6d. each; now approximately 3 3/4d. and has been as low as 1 1/2d. An ell of cloth formerly worth 2 dollars, now *nominally* 28 dollars in consequence of the depreciated paper.

'In Scotland, the *medium of exchange,* not to be confused with the standard of value, in the amount of £1 and upwards may be said to be exclusively paper, and gold does not circulate at all; yet gold is as much the standard of value as if nothing else circulated, because the paper is convertible into the *same fixed quantity* of that metal; and it circulates only on the faith of being so convertible.' (p. 1275.) [58]

'Guineas are *hoarded* in times of distrust.' (Thornton, p. 48.) [59] The *hoarding principle,* in which money functions as independent value, is, apart from the striking forms in which it appears, necessary as *one moment* of exchange resting on money circulation; since everyone, as A. Smith says, needs, beside his own commodity, the medial quantity, a certain proportion of the 'general commodity'. *'The man in trade has property in trade.'* (loc. cit. p. 21.)>

Capital, not labour, *determines the value of the commodity. Torrens*

'Equal capitals or in other words equal quantities of accumulated labour will often put in motion different quantities of immediate labour, but that does not alter the matter.' (p. 31. Torrens, 'An Essay on the Production of Wealth', London, 1821.) ‘In the early period of society … it is the total quantity of labour, accumulated and immediate, expended on production … which *determines the relative value of commodities.* But as soon as stock is accumulated and a class of capitalists distinguishes itself from another class, of workers, when the person who undertakes any branch of industry does not perform his own work, but advances subsistence and materials to others, then it is the amount of capital, or the quantity of accumulated labour expended in production, which determines the exchangeable power of commodities.’ (p. 33, 34.) ‘So long as two capitals are equal … their products are of *equal value,* however we may vary the quantity of immediate labour which they put in motion, or which their products may require. If they are unequal, … their products are of unequal value, though the total quantity of labour expended upon each should be precisely equal.’ (p. 39.) Thus ‘after this separation of capitalists and labourers, it is the amount of capital, the quantity of accumulated labour, and not, as before this separation, the sum of accumulated *and* immediate labour, expended on production, which determines the exchange value.’ (loc. cit.) Mr Torrens’s confusion correct compared to the abstract way of the Ricardians. In itself, fundamentally wrong. Firstly, the determination of value by pure labour time takes place only on the foundation of the production of capital, hence the separation of the two classes. The positing of *prices* as equal, in consequence of the same average rate of profit – and even this with a grain of salt – has *nothing* to do with the determination of value, rather *supposes* the latter. This point important so as to show the Ricardians’ confusion.

The minimum of wages

The rate of surplus value as profit is determined (1) by the magnitude of the surplus value itself; (2) by the relation of living labour to accumulated (the ratio of the capital expended as wages to the capital employed as such). Both the causes which determine (1) and (2), to be examined separately. The law of rent, e.g., belongs to (1). For the time being, necessary labour supposed as such; i.e. that the worker always obtains only the minimum of wages. This supposition is necessary, of course, so as to establish the laws of profit in so far as they are not determined by the rise and fall of wages or by the influence of landed property.

All of these fixed suppositions themselves become fluid in the further course of development. But only by holding them fast at the beginning is their development possible without confounding everything. Besides it is practically sure that, for instance, however the standard of necessary labour may differ at various epochs and in various countries, or how much, in consequence of the demand and supply of labour, its amount and ratio may change, at any given epoch the standard is to be considered and acted upon as a fixed one by capital. To consider those changes themselves belongs altogether to the chapter treating of wage labour.

‘Exchangeable value is determined not by the absolute, but by the relative cost of production. If the cost of producing gold remained the same, while the cost of producing all other things doubled, then would gold have a less power of purchasing all other things than before; and its exchangeable value would fall one half; and this diminution in its exchange value precisely the same in effect as if the cost of producing all other things remained unaltered, while that of producing gold had been reduced one half.’ (p. 56, 57. Torrens, loc. cit.) This important for prices. For determination of value, absolutely not; mere tautology. The value of a commodity is determined by the amount of labour it contains; this means that it exchanges for the same quantity of labour in every other form of use value. It is therefore clear that, if the labour time necessary for the production of object A doubles, then now only 1/2 of it = its earlier equivalent, B. Since equivalence is determined by the equality of labour time or of the amount of labour, the difference of value is of course determined by the inequality of labour time, or, labour time is the measure of value.

1826 cotton machinery and workmen. Hodgskin

‘In 1826, the various machinery used in manufacturing cotton employed 1 man to perform the work of 150. Now suppose that only 280,000 men are employed in it at present; then, half a century earlier, 42,000,000 would have had to be in it.’ (p. 72.) (Hodgskin.) ‘The relative value of the precious metals to other commodities determines how much of them must be given for other things; and the number of sales to be made, within a given period, determines, as far as money is the instrument for effecting sales, the quantity of money required.’

(loc. cit. p. 188.)

'Abundant reason to believe that the practice of coining originated with individuals and carried on by them before it was seized on and monopolized by governments. Such long the case in Russia.' (See Storch.) (loc. cit. p. 195 note.)

Hodgskin is of a different opinion from the romantic Müller: 'The mint stamps only what individuals bring, most injudiciously charging them nothing for the labour of coining; and taxing the nation for the benefit of those who deal in money.' (p. 194. *Popular Polit. Econ.* etc., London, 1827.)

How the machine creates raw material. Linen industry. Tow yarn. **Economist**

After all these digressions about money – and we will occasionally have to take them up again, before ending this chapter – we return to the point of departure. As example of how, in manufacturing industry also, the improvement of machinery and the consequent increase of the force of production creates (relatively) *raw material,* instead of demanding an absolute increase of it: 'The factory system in the linen trade is very recent. Before 1828 the great mass of linen yarn in Ireland and England spun by hand. About this time the flax spinning machine so much improved, especially through the persistence of Mr Peter Fairbairn in Leeds, that it came into very general use. From this time on, spinning mills erected very intensively at Belfast and other parts of Northern Ireland, as in different parts of Yorkshire, Lancashire and Scotland, for spinning fine yarns, and in a few years, spinning by hand given up ... Fine tow yarn now manufactured from what, 20 years earlier, was thrown away as waste.' (*Economist,* 31 Aug. 1850.)

Machinery and surplus labour

With all application of machinery – let us initially look at the case such as it arises directly, that a capitalist puts a part of his capital into machinery rather than into immediate labour – a part of the capital is taken away from its variable and self-multiplying portion, i.e. that which exchanges for living labour, so as to add it to the constant part, whose value is merely reproduced or maintained in the product. But the purpose of this is to make the remaining portion more productive. *First case: the value of the machinery equal to the value of the labour capacity it replaces.* In this case the newly produced value would be diminished, not increased, if the surplus labour time of the remaining part of labour capacity did not grow at the same rate as its amount is diminished. If 50 out of 100 workers are let go and replaced by machinery, then the remaining 50 have to accomplish as much surplus labour time as the 100 did before. If the 100 worked 200 hours' surplus labour time every day out of 1,200 hours' work, then the 50 must now create the same quantity of surplus labour time; hence 4 hours per day, if the former only 2. In that case the surplus labour time remains 50 × 4 = 200, the same as before, 100 × 2 = 200, although the absolute labour time has decreased. In this case, the situation for capital is the same; it is concerned only with the production of surplus labour. In this case, the raw material worked up would remain the same; hence the outlay for it; that for instrument of labour would have increased; that for labour decreased. The value of the total product would be the same, because = to the same sum of objectified and surplus labour time. Such a case would be altogether no incentive for capital. What it would gain in surplus labour time on one side, it would lose on the part of capital which would enter production as objectified labour, i.e. as invariable value. It is also to be kept in mind that the machinery takes the place of more imperfect instruments of production, which possessed a specific value; i.e. had been exchanged for a definite sum of money. The part of the capital employed at a developed stage of the productive force is deducted from the cost of the machinery for the capitalist who sets up a new business, although not for the capitalist who is already in business.

Thus e.g. if, as soon as the machine is introduced for £1,200 (50 labour capacities), an earlier expenditure of, say, 240 pounds for instruments of production ceases to be necessary, then the additional expenditure of capital amounts to only £960; the price of 40 workers a year. In this case then, if the remaining 50 workers together produce exactly as much surplus labour as did the 100 previously, then now 200 hours of surplus labour are produced with a capital of £2,160; before, with a capital of £2,400. The number of workers has decreased by half, absolute surplus labour has remained the same, 200 hours of labour as before; the capital invested in material of labour is also the same; but the relation of surplus labour to the invariable part of the capital has increased absolutely. Altogether £9,240. The relationship is this:

Since the capital laid out in raw material has remained the same, and that laid out in machinery increased, but not in the same relation as that laid out in labour diminished; it follows that the *total outlay of capital diminished;* surplus labour remained the same, hence grown relative to the capital, not only at the rate at which surplus labour time must grow to remain the same with half as many workers, but by more than that; namely by the rate at which the [outlay] for the old means of production is deducted from the costs of the new.

The introduction of machinery or a general increase in the force of production has objectified labour as its substratum, hence costs something; therefore, if a part of the capital previously laid out for labour is laid out as a component part of the part of the capital which enters into the production process as constant value, then the introduction of machinery can take place only if the rate of surplus labour time does not merely remain the same, i.e. grow relative to the living labour employed, but if it grows at a greater rate than the relation between the value of the machinery and the value of the dismissed workers. This can happen either because the entire expenditure incurred for the previous instrument of production must be deducted. In this case the *total sum of the capital laid out diminishes,* and, although the relation of the total sum of employed labour relative to the constant part of the capital has diminished, the surplus labour time has remained the same, and has hence grown not only relative to the capital laid out for labour, for necessary labour time, but also relative to the total capital, to the total value of the capital, because the latter has diminished. Or, the value for machinery may be as great as that previously laid out for living labour, which has now become superfluous; but the rate of surplus labour of the remaining capital has increased so that the 50 workers supply not only as much surplus labour as the 100 did before, but a greater amount. Say, e.g. instead of 4 hours each, 4 1/4 hours. But in this case a greater part of the capital is required for raw materials etc., in short, a greater total capital is required. If a capitalist who previously employed 100 workers for £2,400 annually, lets 50 go, and puts a machine costing £1,200 in their place, then this machine – although it costs him as much as 50 workers did before – is the product of fewer workers, because he pays the capitalist from whom he buys the machine not only the necessary labour, but also the surplus labour. Or, if he had his own workers build the machine, he would have used a part of them for necessary labour only. In the case of machinery, thus, increase of surplus labour with absolute decrease of necessary labour time. It may be accompanied both by absolute diminution of the employed capital, and by its growth.

Capital and profit. ***Value makes the product.*** **– Relation of the worker to the conditions of labour in** ***capitalist production. – All parts of capital bring a profit. – Relation of fixed and circulating capital in the cotton mill. Senior's surplus labour and profit. Tendency of the machine to prolong labour. – Influence of transport on circulation etc. – Transport increasingly suspends hoarding. –*** **Absolute surplus labour and machinery. Senior**

Surplus value, as posited by capital itself and measured by its quantitative relation to the total value of the capital, is *profit.* Living labour, as appropriated and absorbed by capital, appears as capital's own vital power; its self-reproducing power, additionally modified by its own movement, by circulation, and by the time belonging to its own movement, circulation time. Only by distinguishing itself as presupposed value from itself as posited value is capital posited as self-perenniating and multiplying value. Since capital enters wholly into production, and since, as capital, its various component parts are only formally distinct from one another, are equally sums of value, it follows that the positing of value appears to be equally inherent in them. Furthermore, since the part of the capital which exchanges for labour acts productively *only insofar as the other parts of capital are posited together with it* – and since the relation of this productivity is conditioned by the magnitude of the value etc., the various relations of these parts to one another (as fixed capital etc.) – it follows that the positing of surplus value, of profit, appears to be determined by all parts of capital equally. Because on one side the conditions of labour are posited as objective component parts of the capital, on the other side labour itself is posited as activity incorporated in it, the entire labour process appears as capital's own process and the positing of surplus value as its own product, whose magnitude is therefore also not measured by the surplus labour which it compels the worker to do, but rather as a magnified productivity which it lends to labour. The product proper of capital is profit. To that extent, it is now posited as the source of wealth. But in so far as it creates use values, it produces use values, but *use values determined by value:* 'Value makes the product.' (Say.) [60] Accordingly, it produces for consumption. In so far as it eternalizes itself through the constant renewal of labour, it appears as permanent value, a presupposition for production, which latter depends on its preservation. To the extent that it constantly exchanges itself anew for labour, it appears as labour fund. The worker can naturally not produce without the objective conditions of labour. Now, in capital, the latter are separated from him, confront him as independent. He can relate to them as conditions of labour only in so far as his labour itself has previously been appropriated by capital. From the standpoint of capital, the objective conditions of labour do not appear as necessary for the worker; what rather appears as necessary is that *they exist independently opposite him – his separation from them, their ownership by the capitalist* – and that the suspension of this separation takes place only when he cedes his producing power to capital, in exchange for which the latter maintains him as abstract labour capacity, i.e. precisely as the mere capacity of reproducing wealth opposite himself as capital, as the power which rules him.

Thus all parts of the capital bear profit simultaneously, both the circulating part (laid out in wages and raw material etc.) and the part laid out in fixed capital. The capital can now reproduce itself either in the form of circulating capital or in the form of fixed capital. Since we saw earlier, in the examination of circulation, that its value returns in a different form depending on in which of these two forms it is presupposed, and since, from the standpoint of profit-producing capital, what returns is not simply the value, but rather the value of the capital plus the profit, value as itself and value as self-realizing, it follows that the capital will be posited as profit-bearing in a different form corresponding to each of these two forms. The circulating capital enters wholly into circulation, with its use value as vehicle of its exchange value; and thus exchanges for money. I.e. then, it is sold, entirely, although each time only a part of it enters into circulation. In one turnover, however, it has entirely gone over into consumption (whether this be merely individual, or in turn productive) as product, and has completely reproduced itself as value. This value includes the surplus value, which now appears as profit. It is sold as use value, in order to be realized as exchange value. This, then, is *sale at a profit.* On the other side, we have seen that the fixed capital returns only in portions over the course of several years, of several cycles of the circulating capital, and, more specifically, enters into circulation as exchange value and returns as such only to the degree that it is used up (at that time, in the immediate act of production). However, the entry as well as the return of the exchange value is now posited as the entry and return not only of the value of the capital, but also at the same time of the profit, so that a fractional part of profit corresponds to the fractional part of capital.

'The capitalist expects an equal benefit from all parts of the capital he advances.' (Malthus, *Principles of Political Economy,* 2nd ed. Lond., 1836, p. 267.)

'Where Wealth and Value are perhaps the most nearly connected, is in the necessity of the latter to the production of the former.' (loc. cit. p. 301.)

<'The *fixed capital*' (in the cotton factories) 'usually = 1:4 to the circulating, so that if a manufacturer has £50,000, he spends £40,000 in erecting his mill and filling it with machinery, and only £10,000 in the purchase of raw material (cotton, coals etc.) and the payment of wages.' (Nassau W. Senior, *Letters on the Factory Act* etc., 1837, p. 12.) 'The fixed capital is subject to incessant deterioration, not only through wear and tear, but also through constant mechanical improvements ...' (loc. cit.) 'Under present laws, no mill in which persons under 18 years of age are employed can be worked more than 11 1/2 hours by day, i.e. 12 hours for 5 days and 9 on Saturday. Now, the following analysis shows that, in a mill so worked, the whole *net profit* is derived from the *last hour.* Let a manufacturer invest £100,000 – 80,000 in his mill and machinery, and 20,000 in raw material and wages. As to the annual return of the mill, supposing the capital to be turned once a year, and gross profits to be 15%, his goods must be worth £115,000, produced by the constant conversion and reconversion of the £20,000 circulating capital, from money into goods and from goods into money' (in fact the conversion and reconversion of surplus labour first into commodity and then again into necessary labour etc.) 'in periods of rather more than two months. Of these £115,000, each of the 23

half hours of work produces 5/115th or 1/23rd. Of the 23/23, constituting the whole 115,000, 20/23, i.e. £100,000 out of the 115,000, only replace the capital; 1/23 (or 5,000 out of the 115,000) makes up for deterioration of the mill and machinery. The remaining 2/23, i.e. the last 2 of the 23 half hours of every day, produce the net profit of 10%. If, therefore (prices remaining the same), the factory could be kept at work for 13 hours instead of 11 1/2, by an addition of about £2,600 to the circulating capital, the net profit would be more than doubled.' (I.e. 2,600 would be worked up, without requiring relatively more fixed capital, and without payment to *labour at all.* The gross and net profit is = to the material which is worked up for the capitalist *free of charge,* and then of course one hour is = 100% more, if the surplus labour, as Mr Shit [61] falsely presupposes, is only = 1/12 day or only 2/23, as Senior says. 'On the other side, if the daily hours of work were reduced by 1 hour per day (prices remaining the same), *net* profit would be destroyed; if reduced by 1 1/2 hours, gross profit as well. The circulating capital would be replaced, but there would be no fund to compensate the progressive deterioration of the fixed capital.' (12, 13.) (As false as Mr Senior's data, so important his illustration for our theory.) 'The relation of fixed capital to circulating grows constantly for two reasons: (1) the tendency of mechanical improvement to throw on machinery more and more the work of production ... (2) the improvement of the means of transport and the consequent diminution of the stock of raw material in the manufacturer's hands waiting for use. Formerly, when coals and cotton came by water, the incertainty and irregularity of supply forced him to keep on hand 2 or 3 months' consumption. Now, a railway brings it to him week by week, or rather day by day, from the port or the mine. Under such circumstances, I fully anticipate that, in a very few years, the fixed capital, instead of its present proportion, will be as 6 or 7 or even 10 to 1 to the circulating; and, *consequently, that the motives to long hours of work will become greater, as the only means by which a large proportion of fixed capital can be made profitable.* "When a labourer", said Mr Ashworth to me, "lays down his spade, he renders useless, for that period, a capital worth 18d. When one of our people leaves the mill, he renders useless a capital that has cost £100."' (13, 14.)> <This a very nice proof that, under the rule of capital, the application of machinery does not shorten labour; but rather prolongs it. What

it abbreviates is necessary labour, not the labour necessary for the capitalist. Since fixed capital becomes devalued to the extent it is not used in production, its growth is linked with the tendency to make labour *perpetual.* As for the other point raised by Senior, the diminution of the circulating capital relative to the fixed capital would be as great as he assumes if prices remained constant. But if e.g. cotton, on the average, has fallen below its average price, then the manufacturer will purchase as great a supply as his floating capital permits, and vice versa. With coal, however, where production regular and no special circumstances give grounds for anticipating an extraordinary rise in demand, Senior's remark correct. We have seen that transport (and hence means of communication) do not determine circulation, in so far as they concern bringing the product to market or its transformation into commodity. For in this respect they are themselves included as part of the production phase. But they determine circulation in so far as they determine (1) the return; (2) the retransformation of the capital from the money form into that of the conditions of production. The more rapid and uninterrupted the supply of material and *matières instrumentales,* the smaller a supply does the capitalist need to buy. He can therefore all the more often turn over or reproduce the same circulating capital in this form, instead of having it lie around as dormant capital. On the other side, as Sismondi already noted, this also has the effect that the retail merchant, the shopkeeper, can all the more rapidly restore his stock, thus also has less need to keep commodities in stock, because he can renew the supply at any instant. All this shows how with the development of production there is a relative decline of accumulation in the sense of hoarding; increases only in the form of fixed capital, while however continuous simultaneous labour (production) increases in regularity, in intensity, and in scope. The speed of the means of transport, together with their all-sidedness, increasingly transforms (with the exception of agriculture) the necessity of antecedent labour, as far as circulating capital is concerned, into that of simultaneous, mutually dependent, differentiated production. This observation important for the section on accumulation.> *'Our cotton factories, at their commencement, were kept going the whole* 24 *hours.* The difficulty of cleaning and repairing the machinery, and the divided responsibility, arising from the necessity of employing a double staff of overlookers, book-keepers etc. have nearly put an end to this practice, but until Hobhouse's Act reduced them to 69, our factories generally worked from 70 to 80 hours per week.' (p. 15, loc cit.)

Cotton factories in England. Workers. Example for machinery and surplus labour. – Example from Symons. [62] *Glasgow. Power-loom factory etc.* (These examples for the rate of profit.) – Different ways in which machinery *diminishes necessary labour. Gaskell. – Labour the immediate market for capital*

'According to Baines a first-rate cotton-spinning factory cannot be built, filled with machinery, and fitted with steam engines and gas works, under £100,000. A steam-engine of 100 horse-power will turn 50,000 spindles, which will produce 62,500 miles of fine cotton thread per day. In such a factory 1,000 persons will spin as much thread as 250,000 persons could without machinery.' (p. 75. S. Laing, *National Distress etc.,* London, 1844.)

'When *profits fall,* circulating capital is disposed to become to some extent *fixed capital.* When interest 5%, capital not used in making new roads, canals or railways, until these works yield a corresponding large percentage; but when interest only 4 or 3%, capital would be advanced for such improvements, if it obtained but a proportional lower percentage. *Joint-stock companies,* to accomplish great improvements, are the natural offspring of a falling rate of profit. It also induces individuals to *fix* their capital in the form of buildings and machinery.' (p. 232. Hopkins (Th.), *Great Britain for the last 40 Years* etc., London, 1834.) 'McCulloch thus estimates the numbers and incomes of those engaged in the cotton manufacture:

833,000 weavers, spinners, blackers etc. at £24 each a year	£20,000,000
111,000 joiners, engineers, machine makers etc. at £30 each	£3,330,000
Profits, superintendence, coal and materials of machines	£6,670,000
944,000	£30,000,000

'Of the 6 2/3 millions, 2 millions are supposed to go for coal, iron and other materials, for machinery and other outgoings, which would give employment at £30 a year each, to 666,666, making a total population employed of 1,010,666; add to these 1/2 the number of children, aged etc., dependent on those who work, or an additional 505,330; so a total, supported on wages, of 1,515,996 persons. Added to these, those who are supported, directly or indirectly, by the 4 2/3 millions of profit etc.' (Hopkins loc. cit. 336, 337.) According to this calculation, then, 833,000 directly engaged in production; 176,666 in the production of the machinery and the *matières instrumentales* which are required only because of the employment of machinery. The latter are reckoned, however, at £30 per head; thus, so as to resolve their labour into labour of the same quality as that of the 833,000, this must be calculated at £24 per head; thereby, £5,333,000 would give about 222,208 workers; this would give about 1 occupied in the production of machinery and *matières instrumentales* per 3 3/4 occupied in the production of the cotton fabric. Less than 1 to 4, but say 1 to 4. Now, if the 4 remaining workers worked only as much as 5 did earlier, thus each of them 1/4 more surplus labour time, then no profit for capital. The remaining 4 have to supply more surplus labour than the 5 did before; or the number of workers employed for machinery must be smaller than the number of workers displaced by the machinery. Machinery profitable for capital only in relation as it increases the surplus labour time of the workers employed in machinery (not in so far as it reduces it; only in so far as it reduces the relation of surplus labour time to necessary, so that the latter has not only relatively declined, while the number of simultaneous working days has remained the same, but has diminished absolutely).

The increase of absolute labour time supposes the same or an increasing number of simultaneous working days; ditto the increase of the force of production by division of labour etc. In both cases the aggregate labour time remains the same or grows. With the employment of machinery, relative surplus labour time grows not only relative to necessary labour time and hence correlative with aggregate labour time; but rather the relation to necessary labour time grows while aggregate labour diminishes, i.e. the number of simultaneous working days diminishes (relative to surplus labour time).

A Glasgow manufacturer gave Symons (J.C.), author of *Arts and Artisans at Home and Abroad,* Edinb., 1839, the following pieces of information (we cite several of them here in order to have examples for the relation of fixed capital, circulating, the part of the capital laid out in wages, etc.):

Glasgow: 'Expense of *erecting a power-loom factory* of 500 looms, calculated to weave a good fabric of calico, or shirting, such as is generally made in Glasgow, would be about	£18,000
Annual produce, say 150,000 pieces of 24 yards, at 6s.	£45,000
Which cost as under:	
Interest on sunk capital, and for depreciation of value of machinery	1,800
Steam power, oil, tallow, etc. keeping up machinery, utensils, etc.	2,000
Yarns and flax	32,000
Wages to workmen	7,500
Suppose profit	1,700
	£45,000'
	(p. 233)

Thus if we take 5% interest on machinery, then the gross profit 1,700 + 900 = 2,600. The capital laid out in wages amounts, however, to only 7,500. Thus profit relates to wages = 26:75 = 5 1/5:15, hence = 34 2/3%.

'Probable expense of erecting a [spinning] *cotton-mill* with hand mules, calculated to produce No. 40 of [a] fair average quality	£23,000
If patent self-actors, £2,000 additional.	
Produce annually to the present prices of cottons and the rates at which yarns could be sold	25,000
Cost of which as follows:	
Interest of sunk capital, allowance for depreciation of value of the machinery by 10%	2,300
Cotton	14,000
Steam power, oil, tallow, gas, and general expense of keeping up utensils and machinery in repair	1,800
Wages to workers	5,400
Profit	1,500

£25,000’
(p. 234)

(Thus assuming floating capital of £7,000, since 1,500 5% on 30,000.)

‘The produce of the mill taken at 10,000 lb. weekly.’ (234 loc. cit.) Here, then, profit = 1,150 + 1,500 = 2,650:5,400 (wages) = 1:2 2/53, = 49 8/108%.

‘Cost of a *cotton spinning mill of 10,000 throstles*, calculated to produce a fair quality of No. 24	£20,000
Taking present value of produce, the amount would annually be costing	£23,000
Interest on sunk capital, depreciation of value of machinery at 10%	2,000
Cotton	13,300
Steam power, tallow, oil, gas, keeping machinery in repair etc.	2,500
Wages to workers	3,800
Profit	1,400
	£23,000’
	(p. 235)

Hence gross profit = 2,400; wages 3,800; 2,400:3,800 = 24:38 = 12:19 = 63 3/19%.

In the first case 34 2/3%; in the second 49 8/108% and in the last 63 3/19%.

In the first case, wages 1/6 of the total price of the product; in the second more than 1/4; in the last, more than 1/6. But in the first case wages related to the value of the capital as = 1:4 8/15; in the second case = 1:5 15/27; in the third = 1:7 2/19. At the same rate as the total ratio of the part of the capital laid out in wages declines relative to the part laid out in machinery and circulating capital (this, together, 34,000 in the first case; 30,000 in the second; 28,000 in the third), the profit on the part laid out in wages must naturally rise, to allow the percentage of profit to remain the same.

The absolute decrease of aggregate labour, i.e. of the working day multiplied by the number of simultaneous working days, can appear doubly. In the first-cited form, that one part of the hitherto employed workers is dismissed in consequence of the use of fixed capital (machinery). Or, that the introduction of machinery will diminish the *increase* of the working days employed, even though productivity grows and, indeed, at a greater rate (of course) than it diminishes in consequence of the *'value'* of the newly introduced machinery. In so far as the fixed capital has *value,* it does not magnify, but rather diminishes the productivity of labour. 'The surplus hands would enable the manufacturers to lessen the rate of wages; but the certainty that any considerable reduction would be followed by immediate immense losses from turnouts, extended stoppages, and various other impediments which would be thrown in their way, makes them prefer the slower process of mechanical improvement, by which, though they may triple production, they require no new men.' (Gaskell, *Artisans and Machinery,* London, 1836.) (p. 314.) 'When the improvements not quite displace the workmen, they will render one man capable of producing, or rather superintending, the production of quantity now requiring ten or twenty labourers.' (315, loc. cit.) 'Machines have been invented which enable 1 man to produce as much yarn as 250, or 300 even, could have produced 70 years ago: which enable 1 man and 1 boy to print as many goods as a 100 men and a 100 boys could have printed formerly. The 150,000 workmen in the spinning mills produce as much yarn as 40 millions with the one-thread wheel could have produced.' (316, loc. cit.)

'The immediate market for capital, or field for capital, may be said to be labour. The amount of capital which can be invested at a given moment, in a given country, or the world, so as to return not less than a given rate of profits, seems principally to depend on the quantity of labour, which it is possible, by laying out that capital, to induce the then existing number of human beings to perform.' (p. 20. *An Inquiry into those Principles respecting the Nature of Demand* etc., London, 1821.) (By a Ricardian against Malthus's *Principles* etc.)

Alienation of the conditions of labour with the development of capital. (Inversion.) The inversion is the foundation of the capitalist mode of production, not only of its distribution.

The fact that in the development of the productive powers of labour the objective conditions of labour, objectified labour, must grow relative to living labour – this is actually a tautological statement, for what else does growing productive power of labour mean than that less immediate labour is required to create a greater product, and that therefore social wealth expresses itself more and more in the conditions of labour created by labour itself? – this fact appears from the standpoint of capital not in such a way that one of the moments of social activity – objective labour – becomes the ever more powerful body of the other moment, of subjective, living labour, but rather – and this is important for wage labour – that the objective conditions of labour assume an ever more colossal independence, represented by its very extent, opposite living labour, and that social wealth confronts labour in more powerful portions as an alien and dominant power. The emphasis comes to be placed not on the state of being *objectified,* but on the state of being *alienated,* dispossessed, sold [Der Ton wird gelegt nicht auf das *Vergegenständlichtsein,* sondern das *Entfremdet-,* Entäussert-, Veräussertsein]; on the condition that the monstrous objective power which social labour itself erected opposite itself as one of its moments belongs not to the worker, but to the personified conditions of production, i.e. to capital. To the extent that, from the standpoint of capital and wage labour, the creation of the objective body of activity happens in antithesis to the immediate labour capacity – that this process of objectification in fact appears as a process of dispossession from the standpoint of labour or as appropriation of alien labour from the standpoint of capital – to that extent, this twisting and inversion [*Verdrehung und Verkehrung*] is a *real* [*phenomenon*], not a merely *supposed one* existing merely in the imagination of the workers and the capitalists. But obviously this process of inversion is a merely *historical* necessity, a necessity for the development of the forces of production solely from a specific historic point of departure, or basis, but in no way an *absolute* necessity of production; rather, a vanishing one, and the result and the inherent purpose of this process is to suspend this basis itself, together with this form of the process. The bourgeois economists are so much cooped up within the notions belonging to a specific historic stage of social development that the necessity of the *objectification* of the powers of social labour appears to them as inseparable from the necessity of their *alienation vis-à-vis* living labour. But with the suspension of the *immediate* character of living labour, as merely *individual,* or as general merely internally or merely externally, with the positing of the activity of individuals as immediately general or *social* activity, the objective moments of production are stripped of this form of alienation; they are thereby posited as property, as the organic social body within which the individuals reproduce themselves as individuals, but as social individuals. The conditions which allow them to exist in this way in the reproduction of their life, in their productive life's process, have been posited only by the historic economic process itself; both the objective and the subjective conditions, which are only the two distinct forms of the same conditions.

The worker's propertylessness, and the ownership of living labour by objectified labour, or the appropriation of alien labour by capital – both merely expressions of the same relation from opposite poles – are fundamental conditions of the bourgeois mode of production, in no way accidents irrelevant to it. These modes of distribution are the relations of production themselves, but *sub specie distributionis.* It is therefore highly absurd when e.g. J. St. Mill says *(Principles of Political Economy,* 2nd ed., London, 1849, Vol. I, p. 240): 'The laws and conditions of the production of wealth partake of the character of physical truths ... It is not so with the distribution of wealth. That is a matter of human institutions solely.' (p. 239, 240.) The 'laws and conditions' of the production of wealth and the laws of the 'distribution of wealth' are the same laws under different forms, and both change, undergo the same historic process; are as such only moments of a historic process.

It requires no great penetration to grasp that, where e.g. free labour or wage labour arising out of the dissolution of bondage is the point of departure, there machines can only *arise* in antithesis to living labour, as property alien to it, and as power hostile to it; i.e. that they must confront it as capital. But it is just as easy to perceive that machines will not cease to be agencies of social production when they become e.g. property of the associated workers. In the first case, however, their distribution, i.e. that they *do not belong* to the worker, is just as much a condition of the mode of production founded on wage labour. In the second case the changed distribution would start from a *changed* foundation of production, a new foundation first created by the process of history.

Merivale. *Natural dependence of the worker in colonies to be*

replaced by artificial *restrictions*

Gold, in the figurative language of the Peruvians, ‘the tears wept by the sun’. (Prescott.) ‘Without the use of the tools or the machinery familiar to the European, each individual’ (in Peru) ‘could have done but little; but acting in large masses and under a common direction, they were enabled by indefatigable perseverance to achieve results etc.’ (loc. cit.) [63]

<The money prevalent among the Mexicans (more with barter and oriental landed property), ‘a regulated currency of different values. This consisted of transparent quills of gold dust; of bits of tin, cut in the form of a T; and of bags of cocoa, containing a specified number of grains. *“O felicem monetam”*, says Peter Martyr (*de Orbe novo*), *“quae suavem utilemque praebet humano generi potum, et a tartarea peste avaritiae suos immunes servat possessores, quod suffodi aut diu servari nequeat”.’* (Prescott.) [64] ‘Eschwege (1823) estimates the total value of the diamond workings in 80 years at a sum hardly exceeding 18 months’ produce of sugar or coffee in Brazil.’ (Merivale.) [65] ‘The first’ (British) ‘settlers’ (in North America) ‘cultivated the cleared ground about their villages in common … this custom prevails until 1619 in Virginia’ etc. (Merivale, Vol. I. p. 91.) (Notebook, p. 52.) (‘In 1593 the Cortes made the following representation to Philip II: “The Cortes of Valladolid of the year ’48 begged Your Majesty to cease to permit the entry into the kingdom of candles, mirrors, jewellery, knives and similar things from the exterior, these articles, so useless to human life, being exchanged *for gold, as if Spaniards were Indians”.’* (Sempéré.)) [66]

‘In densely peopled colonies the labourer, although free, is naturally dependent on the capitalist; in thinly peopled ones the want of this natural dependence must be supplied by artificial restrictions.’ (Merivale, 314, Vol. II. *Lectures on Colonization* etc., London, 1841, 1842.)>

How the machine etc. saves material. [67] Bread. Dureau de la Malle

Roman money: aes grave pound copper *(emere per aes et libram).* This the *as.* * 485 A.U.C., *deniers d’argent* = 10 *as* (these *denarii* 40 per pound:

in 510, 75 *deniers* per pound; each *denarius* still = 10 *as,* but 10 *as* of 4 ounces each). In 513, the *as* reduced to 2 ounces; the denarius still = 10 *as,* but only 1/84 of the pound of silver. The latter figure, 1/84, held firm until the end of the Republic, but in 537 the denier was 16 *as* to the ounce, and in 665 only 16 *as* the half ounce … The silver *denarius anno* 485 of the Republic = 1 franc 63; 510 = 87 *centimes;* 513 – 707 = 78 *centimes.* From Galba to the Antonines, 1 franc. (Dureau de la Malle, Vol. 1.) At the time of the first silver *denarius,* 1 pound silver to 1 pound copper = 400:1. Beginning of the second Punic war = 112:1. (loc. cit., Vol. I, pp. 82–4.) 'The Greek colonies in the south of Italy drew the silver from which they had fabricated coins since the sixth and fifth century B.C. from Greece and Asia, directly or by way of Tyre and Carthage. Despite this proximity, for political reasons the Romans prohibited the use of gold and silver. The People and the Senate felt that so *easy a medium of circulation* would lead to *concentration,* to decay of the old mores and of agriculture.' (loc. cit. p. 64, 65.) 'According to Varro, the slave an *instrumentum vocale,* the animal *instrumentum semi-mutum,* the plough *instrumentum mutum.'* (loc. cit. p. 253, 254.) (A Roman city-dweller's daily consumption somewhat more than 2 French *livres;* of a countryman, more than 3 *livres.* A Parisian eats 0.93 of bread; a countryman in the 20 departments where wheat the chief staple, 1.70. (loc. cit.) In Italy (today) 1 lb. 8 ounces, where wheat the main food. Why did the Romans eat relatively more? Originally they ate wheat raw or just softened in water; afterwards they decided to roast it … Later they discovered the art of milling, and at first the paste made with this flour was eaten raw. To mill the grain, they used a pestle, or two stones beaten and turned against one another … The Roman soldier prepared a several days' supply of this raw paste, *puls.* Then they invented the winnowing-basket, to clean the grain, and a means was found to separate the bran from the flour; finally they added yeast, and at first they ate the bread raw, until an accident taught them that, by cooking it, one could prevent it from going sour and one could store it much longer. Only after the war against Perseus, 580, did Rome have bakers. (p. 279 loc. cit.) 'In pre-Christian times, the Romans were unacquainted with windmills.' (280 loc. cit.)) 'Parmentier has demonstrated that the art of milling has made great progress in France since Louis XIV, and that the difference between the old and the new millage amounts to 1/2 the bread supplied by the same grain. At first 4, then 3, then 2, then finally 1 1/3 *setiers* of wheat were allotted for the annual consumption of an inhabitant of Paris ... Thus the enormous disproportion between the daily consumption of wheat among the Romans and among us is easily explained by the imperfections of the processes of milling and baking.' (p. 281 loc. cit.) 'The agrarian law was a limitation of landed property among active citizens. The limitation of property formed the foundation of the existence and prosperity of the old republics.' (loc. cit. p. 256, 257.) 'The state's revenue consisted of the estates, of contributions in kind, of forced labour, and of some taxes in silver payable at the entry and exit of merchandise, or levied on the sale of certain goods. This mode ... still exists almost without change in the Ottoman Empire ... At the time of Sulla's dictatorship and even at the end of the seventh century A.U.C., the Roman Republic took in only 40 million francs annually, *anno* 697 ... In 1780, the revenue of the Turkish Sultan, in coined piastres, only 35,000,000 piastres or 70 million francs ... The Romans and the Turks levied the bulk of their revenue in kind. Among the Romans ... 1/10 of the grain, 1/5 of the fruit, among the Turks, varying from 1/2 to 1/10 of the product ... Since the Roman Empire was only an immense agglomeration of independent municipalities, the greater part of the costs and expenditures remained communal.' (pp. 402–7.) (The Rome of Augustus and Nero, without the suburbs, only 266,684 inhabitants. Assumes that in the fourth century of the Christian era the suburbs had 120,000 inhabitants, the Aurelian belt 382,695, altogether 502,695, 30,000 soldiers, 30,000 aliens; altogether 562,000 heads, in round numbers. *Madrid,* during a period of 1 1/2 centuries after Charles V, capital of a part of Europe and of half the new world, many resemblances to Rome. Its population also did not grow in proportion to its political importance. (405, 406, loc. cit.)) 'The social condition of the Romans at the time resembled much more that of Russia or of the Ottoman Empire than that of France or of England: little commerce or industry; immense fortunes side by side with extreme misery.' (p. 214, loc. cit.) (Luxury only in the capital and in the residences of the Roman satraps.) 'From the destruction of Carthage to the foundation of Constantinople, Roman Italy had existed in the same condition, *vis-à-vis* Greece and the Orient, as was Spain during the eighteenth century *vis-à-vis* the rest of Europe. Alberoni said: "Spain is to Europe what the mouth is to the body: everything enters, nothing stays”.’ (loc. cit. p. 385 seq.)

[*] *as* or *libra* = 12 ounces; 1 ounce = 24 *scrupula;* 288 *scrupula* per pound.

Usury originally unrestricted in Rome. The law of the 12 tables (303 A.U.C.) had fixed the interest on money at 1% per year (Niebuhr says 10). [68] These laws promptly violated. Duilius (398 A.U.C.) again reduced the interest on money to 1%, *unciario faenore.* [69] Reduced to 1/2% in 408; in 413, lending at interest was absolutely forbidden by a plebiscite engineered by the tribune, Genucius. It is not surprising that, in a republic where industry, where commerce either wholesale or retail were prohibited to citizens, there was also a prohibition against *commerce in money.* (p. 260, 261 Vol. II, loc. cit.) This situation lasted 3 years, until the capture of Carthage. 12%, then: 6% the average annual rate of interest. (261 loc. cit.) Justinian fixed interest at 4%; ... *usura quincunx* [70] under Trajan the legal interest is 5%. Commercial interest in Egypt, 146 years B.C., was 12%. (loc. cit. p. 263.)

The involuntary alienation of feudal landed property develops with usury and with money: ‘The introduction of money which buys all things, and hence the advantage for the creditor, who lends money to the land owner, brings in the necessity of legal alienation for the advance.’ (124. John Dalrymple, *An Essay towards a General History of Feudal Property in Great Britain,* 4th ed., Lond., 1759.)

In medieval Europe: ‘Payments in gold customary with only a few articles of commerce, mostly with precious goods. Most prevalent outside the mercantile sphere, with gifts by the great, certain high obligations, heavy fines, purchase of landed estates. *Unminted* gold was not infrequently measured to suit in pounds or marks (half pounds) ... 8 ounces = 1 mark; one [ounce] hence = 2 pennyweight or 3 carats. Of *minted gold* until the Crusades, familiar only with the Byzantine *solidus,* the Italian *Tari* and the Arabian *maurabotini*’ (afterwards *maravedi*). (Hüllmann, *Städtewesen des Mittelalters,* 1st Part, Bonn, 1826.) (p. 402–4.) ‘In Frankish laws, the *solidus* also as *mere money of account,* in which the value of agricultural products to be paid as fines was expressed. E.g. among the Saxons, a *solidus* a yearling ox in usual autumn condition ... In Ripuarian law, a healthy cow represented one *solidus* ... 12 *denars* = 1 gold *solidus.*’ (405, 406.) 4 *Tari* = 1 Byzantine *solidus* ... Since the thirteenth century, various gold coins minted in Europe. *Augustales* (of the emperor *Frederick II* in Sicily: Brundisium and Messina); *florentini* or *floreni* (Florence 1252); … *ducats* or *zecchini* (Venice since 1285). (409–11, loc. cit.) 'Larger gold coins minted also in Hungary, Germany and the Netherlands since the fourteenth century; in Germany, were simply called *Gulden*.' (loc. cit. 413.) '*With payments in silver,* the prevailing custom in all larger payments was weighing, usually in marks … Even minted silver weighed for such payments, since the coin still of almost wholly pure silver, hence weight the only question. Hence the name *pound (livre, lire)* * and mark, partly the name of imaginary or accounting coins, partly passed over to real silver coins. *Silver coins: denari* or *kreuzer …* In Germany these denari were called *Pfennige* (Penig, Penning, Phennig) … since as early as the ninth century. Originally Pending, Penthing, Pfentini … from pfündig, in the old form pfünding … the same as full-weighted: hence pfündige denari, abbreviated pfündinge … Another name for the denari, from the beginning of the twelfth century in France, Germany, Netherlands, England, from the star pictured on them in place of the cross: *sternlinge, sterlinge, starlinge …* Denari sterlings = pfennig sterlings … In the fourteenth century, 320 of the Netherlands sterlings made a pound, 20 to the ounce … *In the earlier Middle Ages, silver solidi not real coins, but rather inclusive name for 12 denari …* 1 gold solidus = 12 sterling denari, for this was the median relation of gold and silver … Oboli, half pfennigs, having circulated as *small change …* With the increasing spread of petty trade, more and more of the small commercial cities and petty princes obtained the right to strike their own local coin, thus for the most part small change. Alloyed it with copper, in increasing proportions … Thick pennies, gros deniers, grossi, groschen, groten, first minted in Tours before the middle of the thirteenth century. These groschen originally double pfennigs.' (415–33.)

* *Notabene*: In Mexico we found money but no weights; in Peru weights but no money.

'The ecclesiastical assessments levied by the popes on nearly all Catholic countries contributed in no small measure, firstly, to the development of the entire money system in commercially active Europe, and then, as a consequence, to the rise of a variety of efforts to circumvent the ecclesiastical prohibition (of interest). The pope made use of the Lombards in the collection of official dues and other obligations from the archbishoprics. These, the chief usurers and pawnbrokers, under papal protection. Already generally known since the middle of the twelfth century. Especially from Siena. "Public *usurarii*." In England they called themselves "Roman Pontifical Money-Dealers". Some bishops in Basle and elsewhere pawned the episcopal ring, silken robes, all the ecclesiastical vessels at low rates with Jews, and paid interest. But bishops, abbots, priests themselves also practised usury with the church vessels by lending them for a share of the gain to Tuscan money dealers from Florence, Siena and other cities.' etc. (see loc. cit. Notebook, p. 39.) [71]

Because money is the *general equivalent, the general power of purchasing,* everything can be bought, everything may be transformed into money. But it can be transformed into money only by being alienated [*alieniert*], by its owner divesting himself of it. Everything is therefore alienable, or indifferent for the individual, external to him. Thus the so-called *inalienable, eternal* possessions, and the immovable, solid property relations corresponding to them, break down in the face of money. Furthermore, since money itself exists only in circulation, and exchanges in turn for articles of consumption etc. – for values which may all ultimately be reduced to purely individual pleasures, it follows that everything is valuable only in so far as it exists for the individual. With that, the independent value of things, except in so far as it consists in their mere being for others, in their relativity, exchangeability, the absolute value of all things and relations, is dissolved. Everything sacrificed to egotistic pleasure. For, just as everything is alienable for money, everything is also obtainable by money. Everything is to be had for 'hard cash', which, as itself something existing external to the individual, is to be catched [sic] by fraud, violence etc. Thus everything is appropriable by everyone, and it depends on chance what the individual can appropriate and what not, since it depends on the money in his possession. With that, the individual is posited, as such, as lord of all things. There are no absolute values, since, for money, value as such is relative. There is nothing inalienable, since everything alienable for money. There is no higher or holier, since everything appropriable by money. The *'res sacrae'* and *'religiosae',* which may be *'in nullius bonis', 'nec aestimationem recipere, nec obligari alienarique posse',* which are exempt from the '*commercio hominum',* [72] do not exist for money – just as all men are equal before God. Beautiful that the Roman church in the Middle Ages itself the chief propagandist of money.

‘Since the ecclesiastical law against usury had long lost all significance, in 1425 Martin formally annulled it.’ (Hüllmann, part II, loc. cit. Bonn, 1827, p. 55.) ‘No country in the Middle Ages a general rate of interest. Firstly, the priests strict. Uncertainty of the juridical arrangements for securing the loan. Accordingly higher rates in individual cases. The small circulation of money, the necessity to make most payments in cash, since the brokerage business still undeveloped. Hence great variety of views about interest and concepts of usury. In Charlemagne’s time it was considered usurious only when 100% was taken. At Lindau on Lake Constance, in 1344, local citizens took 216 2/3%. In Zurich the Council fixed the legal interest at 43 1/3% … In Italy, 40% had to be paid during some periods, although from the twelfth to the fourteenth century the usual rate does not exceed 20% … Frederick II in his decree … 10%, but this only for Jews. He did not wish to speak for the Christians … 10% was already usual in the thirteenth century in the Rhineland of Germany.’ (55–7 loc. cit.)

Productive consumption. Newman. – Transformations of capital. Economic cycle. (*Newman*)

‘*Productive consumption,* where the consumption of a commodity is *a part of the process of production.*’ (Newman etc. Notebook XVII, 10.) [73] ‘It will be noticed, that in these instances *there is no consumption of value,* the same value existing under a new form.’ (loc. cit.) ‘Further *consumption* … the appropriation of individual revenue to its different uses.’ (p. 297.) (loc. cit.)

‘*To sell for money* shall at all times be made so easy as it is now *to buy with money,* and production would become the uniform and never failing cause of demand.’ (John Gray, *The Social System* etc., Edinburgh, 1831.) (p. 16.) ‘After land, capital, labour, the fourth necessary condition of production is: *instant power of exchanging.*’ (loc. cit. 18.) ‘To be able to *exchange* is’ for the man in society ‘as important as it was to Robinson Crusoe to be able to *produce.*’ (loc. cit. 21.)

‘According to Say, credit only transfers capital, but does not create any. This true only in the one case of a loan to an industrialist by a capitalist … but not of credit between producers in their mutual advances. What one producer advances to another is not capital; it is products, commodities. These products, these commodities, can and undoubtedly will become active capital in the hands of the borrower, i.e. instruments of labour, but at the time they are nothing but products for sale in the hands of their owner, and everywhere inactive … One must distinguish … between product and commodity … and instrument of labour and productive capital … As long as a product remains in the hands of its producer, it is only a commodity, or, if you like, inactive, inert capital. Far from being of benefit for the industrialist who holds it, it is a burden for him, a ceaseless cause of trouble, of *faux frais* and of losses: storage costs, maintenance costs, protection costs, interest on capital etc., without counting the waste and spoiling which nearly all commodities suffer when they are inactive for long … Thus, if he sells this, his commodity, on credit, to another industrialist who can use the commodities for the kind of work for which they are fit, then, from having been inert commodities, they have become, for the latter, active capital. In this case, therefore, there will be an increase of productive capital on one side without any diminution on the other. Even more: if one takes note that the seller, while furnishing his commodity on credit, has received in exchange a bill which he has the right to negotiate on the spot, is it not clear that by that very fact he too has obtained the means to renew his raw materials and his instruments of labour so as to begin work again? Thus there is here a double growth of productive capital, in other words, a power acquired on both sides.' (Charles Coquelin, 'Du Crédit et des Banques dans l'Industrie', *Revue des deux mondes,* Vol. 31, 1842, p. 799 *seq.)* 'Let the whole mass of commodities for sale pass rapidly from the state of inert product into that of active capital, without delays and obstacles: the country will be filled with so much new activity! … this rapid transformation is precisely the advantage which credit allows to be realized … This is the *activity of circulation …* Thus credit may increase the industrialists' business tenfold … In a given period of time, the dealer or producer renews his materials and his products ten times instead of once … Credit brings this about by increasing everyone's purchasing power. Instead of reserving this power to those who presently have the ability to pay, it gives it to all those people … whose position and whose morality provide the guarantee of a future payment; it gives it to any person who is capable of utilizing these products through labour … Hence the first benefit of credit is to increase, if not the sum of values a country possesses, yet at least the sum of active values. This is the immediate effect. Flowing out of it … is the increase of the productive powers, hence also of the sum of values etc.' (loc. cit.)

Letting is a conditional sale, or sale of the use of a thing for a limited time. (Corbet, Th., *'An Inquiry into the Causes and Modes of the Wealth of Individuals'* etc., Lond., 1841, p. 81.)

'Transformations to which capital is subjected in the work of production. Capital, to become productive, must be consumed.' (p. 80. S. P. Newman, *Elements of Political Economy,* Andover and New York, 1835.) *'Economic cycle …* the whole course of production, from the time that outlays are made, till returns are received. In agriculture, seed time is its commencement, and harvesting its ending'. (81). *The basis of the difference between fixed and circulating* capital is that during every economic cycle, a part is partially, and another part totally consumed. (loc. cit.) *Capital as directed to different employments.* (loc. cit.) Belongs in the doctrine of competition. *'A Medium of Exchange:* In undeveloped nations, whatever commodity constitutes the larger share of the wealth of the community, or from any cause becomes more frequently than others an object of exchange, is wont to be used as a circulating medium. So cattle a medium of exchange among pastoral tribes, dried fish in Newfoundland, sugar in the West Indies, tobacco in Virginia. *Precious metals …* advantage … : (a) sameness of quality in all parts of the world … (b) admit of minute division and exact apportionment; (c) rarity and difficulty of attainment, (d) they admit of coinage.' (100 loc. cit.)

Dr Price. *Innate power of capital*

The notion of capital as a self-reproducing being – as a value perenniating and increasing by virtue of an innate quality – has led to the marvellous inventions of Dr Price, which leaves the fantasies of the alchemists far behind, and which Pitt earnestly believed and made into the pillars of his financial sagacity in his sinking fund laws (see Lauderdale). [74] The following, a few striking excerpts from the man:

'Money bearing compound interest increases at first slowly. But, the rate of increase being continually accelerated, it becomes in some time so rapid, as to mock all the powers of the imagination. One penny, put out at our Saviour's birth to 5% compound interest, would, before this time, have increased to a greater sum than would be obtained in a 150 millions of Earths, all solid gold. But if put out to simple interest, it would, in the same time, have amounted to no more than 7 shillings 4 1/2d. Our government has hitherto chosen to improve money in the *last,* rather than the first of these ways.' (18, 19. Price, Richard, *An Appeal to the Public on the Subject of the National Debt,* London, 1772, 2nd ed.) (His secret: the government should borrow at simple interest, and lend out the borrowed money at compound interest.) In his *Observations on Reversionary Payments* etc., London, 1772, he flies even higher: 'A shilling put out to 6% compound interest at our Saviour's birth would ... have increased to a greater sum than the whole solar system could hold, supposing it a sphere equal in diameter to the diameter of Saturn's orbit.' (loc. cit. XIII, note.) 'A state need never, therefore, be under any difficulties; for, with the *smallest* savings, it may, in as little time as its interest can require, pay off the largest debts.' (p. xiv.) The good Price was simply dazzled by the enormous quantities resulting from geometrical progression of numbers. Since he regards capital as a self-acting thing, without any regard to the conditions of reproduction of labour, as a mere self-increasing number, he was able to believe that he had found the laws of its growth in that formula (see below). Pitt, 1792, in a speech where he proposed to increase the sum devoted to the sinking fund, takes Dr Price's mystification quite seriously. ($S = C\,(1 + i)^n$.)

McCulloch, in his *Dictionary of Commerce,* 1847, cites, as properties of metallic money: 'The material must be: (1) divisible into the smallest portions; (2) capable of being stored for an indefinite period without deterioration; (3) easily transportable from place to place owing to great value in small bulk; (4) a piece of money, of a certain denomination, always equal in size and quality to every other piece of the same denomination; (5) its value comparatively steady.' (581.) [75]

Proudhon. Capital and simple exchange. Surplus. – *Necessity of workers' propertylessness. Townsend. Galiani. – The* infinito *in process.* Galiani

In the whole polemic by Mr Proudhon against Bastiat in *Gratuité du crédit. Discussion entre M. Fr. Bastiat et M. Proudhon,* Paris, 1850, Proudhon's argument revolves around the fact that lending appears as something quite different to him from selling. To lend at interest 'is the ability of selling the same object again and again, and always receiving its price anew, without ever giving up ownership of what one sells'. (9, in the first letter [to] Chevé, one of the editors of *La Voix du Peuple*.) [76] The different form in which the reproduction of capital appears here deceives him into thinking that this constant reproduction of the capital – whose price is always obtained back again, and which is always exchanged anew for labour at a profit, a profit which is realized again and again in purchase and sale – constitutes its concept. What leads him astray is that the 'object' does not change owners, as with purchase and sale; thus basically only the form of capital lent at interest with the form of reproduction peculiar to fixed capital. With house rent, about which Chevé speaks, it is directly the form of fixed capital. If the circulating capital is regarded in its whole process, then it may be seen that, although *the same object* (this specific pound of sugar, e.g.) is not always sold anew, the same value does always reproduce itself anew, and the sale concerns only the form, not the substance. People who are capable of making such objections are obviously still unclear about the first elementary concepts of political economy. Proudhon grasps neither how profit, nor, therefore, how interest, arises from the laws of the exchange of values. 'House', money etc. should therefore not be exchanged as 'capital', but rather as 'commodity … at cost price'. (44.) (The good fellow does not understand that the whole point is that value is exchanged for labour, according to the law of values; that, hence, to abolish interest, he would have to abolish *capital* itself, the mode of production founded on exchange value, hence wage labour as well. Mr Proudhon's inability to find even one difference between loan and sale: 'In effect, the hatter who sells hats … obtains their value in return, neither more nor less. But the lending capitalist … not only gets back the whole of his capital; he receives more than the capital, more than he brings into the exchange; he receives an interest above the capital.' (69.) Thus Mr Proudhon's hatters reckon neither profit nor interest as part of their cost price. He does not grasp that, precisely by receiving the *value* of their hats, they obtain more than these cost them, because a part of this value is appropriated in the exchange, without equivalent, with labour. Here also his great thesis mentioned above: ‘Since in commerce, the interest on capital is added to the worker’s wages to make up the price of the commodity, it is impossible for the worker to buy back what he has himself produced. To live by working is a principle which, under the reign of interest, implies a contradiction.’ (105.) In letter IX (p. 144–52), the good Proudhon confuses money as medium of circulation with capital, and therefore concludes that the ‘capital’ existing in France bears 160% (namely 1,600 millions annual interest in the state debt, mortgage etc. for a capital of a thousand millions, … the sum of currency … circulating in France). How little he understands about capital in general and its continual reproduction [is shown by] the following, which he imputes as specific to money-capital, i.e. to money lent out as capital: ‘Since, with the accumulation of interest, money-capital, exchange after exchange, always comes back to its source, it follows that this re-lending, always done by the same hand, always profits the same person.’ (154.) *‘All labour must leave a surplus.’* (Everything ought to be *sold,* nothing *lent.* This the simple secret. Inability to see how the exchange of commodities rests on the exchange between capital and labour, and profit and interest in the latter. Proudhon wants to cling to the simplest, most abstract form of exchange.)

The following pretty demonstration by Mr Proudhon: ‘Since value is nothing more than a proportion, and since all products are necessarily proportional to one another, it follows that from the social viewpoint products are always values and produced values: for society, the difference between capital and product does not exist. This difference is entirely subjective to individuals.’ (250.)

The antithetical nature of capital, and the necessity for it of the propertyless worker, is naïvely expressed in some earlier English economists, e.g. the Reverend Mr J. Townsend, [77] the father of population theory, by the fraudulent appropriation of which Malthus (a shameless plagiarist generally; thus e.g. his theory of rent is borrowed from the farmer, Anderson) made himself into a great man. Townsend says: ‘It seems to be a *law of nature* that the poor should be to a certain degree improvident, that there may be always some to fulfil the most servile, the most sordid, and the most ignoble offices in the community. The stock of human happiness is thereby much increased. The more delicate ones are thereby freed from drudgery, and can pursue higher callings etc. undisturbed.' (A *Dissertation on the Poor-laws,* edition of 1817, p. 39.) 'Legal constraint to labour is attended with too much trouble, violence, and noise, creates ill will etc., whereas hunger is not only a peaceable, silent, unremitted pressure, but, as the most natural motive to industry and labour, it calls forth the most powerful exertions.' (15.) (This the answer to what labour is in fact more productive, the slave's or the free worker's. A. Smith could not raise the question, since the mode of production of capital presupposes free labour. On the other side, the developed relation of capital and labour confirms A. Smith in his distinction between productive and unproductive labours. Lord Brougham's stale jokes against it, and the objections, supposed to be serious, by Say, Storch, MacCulloch and *tutti quanti* do not make any impact on it. A. Smith misses the mark only by somewhat too crudely conceiving the objectification of labour as labour which fixates itself in a tangible [*handgreiflich*] object. But this is a secondary thing with him, a clumsiness in expression.)

With Galiani, too, the workmen are supplied by a law of nature. Galiani published the book in 1750. 'God makes sure that the men who exercise occupations of primary utility are born in abundant numbers.' (78. *Della Moneta,* Vol. III, Scrittori Classici Italiani di Economia Politica. Parte Moderna. Milano, 1803.) But he already has the correct concept of value: 'It is only toil which gives value to things.' (74.) Of course, labour is distinct qualitatively as well, not only in so far as it [is performed] in different branches of production, but also more or less intensive etc. The way in which the equalization of these differences takes place, and all labour is reduced to unskilled simple labour, cannot of course be examined yet at this point. Suffice it that this reduction is in fact *accomplished* with the positing of products of all kinds of labour as values. As values, they are equivalents in certain proportions; the higher kinds of labour are themselves appraised in simple labour. This becomes clear at once if one considers that e.g. Californian gold is a product of simple labour. Nevertheless, every sort of labour is paid with it. Hence the qualitative difference is suspended, and the product of a higher sort of labour is in fact reduced to an amount of simple labour. Hence these computations of the different qualities of labour are completely a matter of indifference here, and do not violate the principle. 'Metals ... are used for money because they are valuable, … they are not valuable because they are used for money.' (loc. cit. 95.) 'It is the velocity of circulation of money, and not the quantity of metal, which makes more or less money appear.' (99.) 'Money is of two kinds, *ideal and real;* and is adapted to two uses, to *evaluate* things and to *purchase* them. Ideal money is as good as, sometimes better than, real money for evaluating things … the other use of money is to buy those things to which its value may be equal … prices and contracts are valued in ideal money and executed in real.' (p. 112 seq.) *'The metals have the peculiar and singular quality that in them alone all relations reduce themselves to one only, which is their quantity; nature did not endow them with a varying quality either in their internal constitution or in their external form and shape.'* (126, 127.) This is very important observation. Value supposes a common substance, and all differences, proportions etc. reduced to merely quantitative ones. This the case with precious metals, which thus appear as the natural substance of value. 'Money … like a law which reduces all things to their necessary proportions is that which articulates all things in a single voice: *price.'* (152.) 'Only this same ideal money is *of account,* which is to say, all things are stipulated, contracted and evaluated in it; which came about for the same reason that the moneys which are ideal today are the most ancient moneys of a nation, and all of them were once real, and, because they were real, they were used in accounting.' (152.) (This also the formal clarification of Urquhart's ideal money etc. For the blacks etc. the iron bar was originally real money, then changed into ideal; but they tried at the same time to hold onto its previous value. Now, since the value of iron, as becomes apparent to them in commerce, fluctuates relative to gold etc., therefore the ideal bar, so as to preserve its original value, expresses varying proportions of real amounts of iron, a laborious calculation which does honour to these gentlemen's power of abstraction.) (In the debates caused by the Bullion Committee 1810, Castlereagh advanced similar confused notions.) A beautiful statement by Galiani: 'The infinity which' (things) 'lack in progression, they find in circulation.' (156.)

About use value, Galiani nicely says: 'Price is a relation … the price of things is their proportion relative to our need, which has as yet no fixed measure. But this will be found. I myself believe it to be *man himself.'* ([159,] 162.) 'Spain, during the same period when it was the greatest as well as the richest power, counted in reales and in the tiniest maravedis.’ (172, 173.) ‘It is, rather, he’ (man) ‘who is the sole and true wealth.’ (188.) *‘Wealth is a relation between two persons.’* (221.) ‘When the price of a thing, or rather its proportion relative to others, changes proportionately to all of them, it is a clear sign that it is its value alone, and not that of all the others, which has changed.’ (154.) (The costs of preserving the capital, of repairing it, also have to be taken into account.)

‘The *positive limitation of quantity in paper* money would accomplish the only useful purpose that cost of production does in the other.’ (Opdyke.) [78] The merely quantitative difference in the material of money: ‘Money is returned *in kind only*’ (with loans); ‘which fact distinguishes this agent from all other machinery ... indicates the nature of its service ... clearly proves the singleness of its office.’ (267.) ‘With money in possession, we have but one exchange to make in order to secure the object of desire, while with other surplus products we have two, the first of which (securing the money) is infinitely more difficult than the second.’ (287, 288.)

‘Banker ... differs from the old *usurer ...* that he lends to the rich and seldom or never to the poor. Hence he lends with less risk, and can afford to do it on cheaper terms; and for both reasons, he avoids the popular odium which attended the usurer.’ (44.) (Newman, F. W., *Lectures on Political Economy,* London, 1851.)

Advances. *Storch.* – Theory of savings. *Storch.* – MacCulloch. *Surplus.* – *Profit.* – Periodical destruction of capital. *Fullarton.* – Arnd. *Natural interest*

Everyone hides and buries his money quite secretly and deeply, but especially the *Gentiles,* who are the almost exclusive masters of commerce and of money, and who are infatuated with this belief that the gold and silver they hide during their lifetime will be of use to them after death. (314.) (François Bernier, Vol. I, *Voyages contenant la description des états du Grand Mogol* etc., Paris, 1830.)

Matter in its natural state ... is always *without value ...* Only through labour does it obtain exchange value, become element of wealth. (MacCulloch, *Discours sur l'origine de l'économie politique* etc. transl. by Prévost. Geneva and Paris, 1825. p. 57.)

Commodities in exchange are each other's *measure.* (Storch. *Cours d'Économie Politique* avec des notes etc. par J. B. Say, Paris, 1823, Vol. I, p. 81.) 'In the trade between Russia and China, silver is used to evaluate all commodities; nevertheless, this commerce is carried on by barter.' (p. 88.) 'Just as labour is not the *source …* of wealth, so is it not its *measure.'* (p. 123 loc. cit.) 'Smith … let himself be misled into the opinion that the same cause which made material things *exist* was also the source and the measure of value.' (p. 124.) 'Interest the price one pays for the use of a capital.' (p. 336.) Currency must have a direct value, but be founded on an artificial need. Its material must not be indispensable for human existence; because the whole amount of it which is used for currency cannot be used individually, and must always circulate. (Vol. II, p. 113, 114.) 'Money takes the place of anything.' (p. 133.) T.V. [79] *Considérations sur la nature du revenu national,* Paris, 1824: 'Reproductive consumption is not properly an expense, but only an *advance,* because it is reimbursed to him who makes it.' (p. 54.) 'Is there not a manifest contradiction in this proposition that a people grows wealthy by its savings, or its *privations,* that is to say, by voluntarily condemning itself to poverty?' (p. 176.) 'At the time when hides and pelts served as money in Russia, the inconvenience involved in circulating so voluminous and perishable a currency gave rise to the idea of replacing them by small pieces of stamped leather, which thereby became symbols payable in hides and pelts … They kept up this usage until 1700' (namely, later, of representing the fractions of silver kopecks), 'at least in the city of Kaluga and its environs, until Peter I' (1700) 'ordered them to be turned in and exchanged for small copper coins.' (Vol. IV, p. 79.)

An indication of the marvels of compound interest is already found in the great seventeenth-century champion of the fight against usury: in Jos. Child. *Traités sur le commerce* etc. trad. de l'anglois (English publication 1669, Amsterdam and Berlin, 1754.) (pp. 115–17.)

'In point of fact a commodity will always exchange for more labour than has produced it; *and it is this excess that constitutes profits.'* (p. 221. McCulloch, *The Principles of Political Economy,* London, 1830.) Shows how well Mr McCulloch has understood the Ricardian principle. He distinguishes between *exchange value* and *real value;* the former (1) quantity of labour expended in its appropriation or production; (2) the second, *buying power* of certain quantities of labour of the other commodities. (p. 211.) Man is as much the *produce of labour* as any [of] the machines constructed by his agency; and it appears to us that in all economical investigations he ought to be considered in precisely the same point of view. (115 loc. cit.) Wages ... really consist of a part of the produce of the industry of the labourer. (p. 295.) The profits of capital are only another name for the wages of accumulated labour. (p. 291.)

‘A periodical destruction of capital has become a necessary condition of any market rate of interest at all, and, considered in that point of view, these awful visitations, to which we are accustomed to look forward with so much disquiet and apprehension and which we are so anxious to avert, may be nothing more than the natural and necessary corrective of an overgrown and bloated opulence, the *vis medicatrix* by which our social system, as at present constituted, is enabled to relieve itself from time to time of an ever-recurring plethora which menaces its existence, and to regain a sound and wholesome state.’ (p. 165. Fullarton (John): *On the Regulation of Currency* etc. Lond., 1844.)

Money – *General Power of Purchasing.* (Chalmers.) [80]

‘*Capital ...* services and commodities used in production. *Money:* the measure of value, the medium of exchange, and the universal equivalent; more practically: the *means of obtaining capital; the only means of paying for capital* previously obtained for credit; virtually – security for obtaining its equivalent value in capital: *Commerce* is the exchange of capital for capital through the medium of money, and the contract being for the medium, money alone can satisfy the contract and discharge the debt. In selling, one kind of capital is disposed for money for obtaining its equivalent value in any kind of capital. *Interest* – the consideration given for the loan of money. If the money is borrowed for the purpose of *procuring capital,* then the consideration given is a remuneration for the use of capital (raw materials, labour, merchandise etc.), which it obtains. If borrowed for the purpose of discharging a debt, for paying for capital previously obtained and used (contracted to be paid for in money), then the consideration given is for the use of money itself, and in this respect interest and discount are similar. *Discount* solely the remuneration for money itself, for converting credit money into real money. A good bill gives the same command over capital as bank notes, minus the charge for discount; and bills are discounted for the purpose of obtaining money of a more convenient denomination for wages and small cash payments, or to meet larger engagements falling due; and also for the advantage to be gained when ready money can be had by discounting at a lower rate than 5%, the usual allowance made for cash. The main object, however, in discounting depends fundamentally upon the supply and demand of legal tender money … The rate of interest depends mainly on the demand and supply of capital, and the rate of discount entirely on the supply and demand of money.' (13 March '58, *Economist,* letter to the editor.)

Mr K. Arnd, quite in his proper place where he reasons about the 'dog tax', [81] has made the following interesting discovery:

'In the natural course of the production of goods, there is only *one* phenomenon, which – in wholly settled and cultivated countries – seems destined to regulate the rate of interest to some extent; – this is the rate at which the amount of timber in the European forests increases with their annual new growth – this growth proceeds, quite independently of its exchange value, at the rate of 3 to 4 per cent.' (p. 124, 125. *Die naturgemässe Volkswirtschaft* etc., Hanau, 1845.) This deserves to be called the forest-primeval [*waldursprüngliche*] rate of interest.

Interest and profit. – Carey. *Pawning in England*

‘The remaining value or overplus will in each trade be in proportion to the value of the capital employed.’ (Ricardo.) [82]

In regard to *interest,* two things are to be examined: *Firstly,* the division of *profit* into interest and profit. (As the unity of both of these the English call it *gross profit.*) The difference becomes perceptible, tangible as soon as a class of monied capitalists comes to confront a class of industrial capitalists. *Secondly: Capital* itself becomes a commodity, or the commodity (money) is sold as capital. Thus it is said e.g. that capital, like any other commodity, varies in price according to demand and supply. These then determine the rate of interest. Thus here capital as such enters into circulation.

Monied capitalists and industrial capitalists can form two particular classes only because profit is capable of separating off into two branches of revenue. The two kinds of capitalists only express this fact; but the split has to be there, the separation of profit into two particular forms of revenue, for two particular classes of capitalists to be able to grow up on it.

The form of interest is older than that of profit. The level of interest in India for communal agriculturists in no way indicates the level of profit. But rather that profit as well as part of wages itself is appropriated in the form of interest by the usurer. It requires a sense of history like that of Mr Carey to compare this interest with that prevailing on the English money market, which the English capitalist pays, and to conclude therefrom how much higher the ‘labour share’ (the share of labour in the product) is in England than in India. He ought to have compared the interest which English handloom-weavers, e.g. in Derbyshire, pay, whose material and instrument is advanced (lent) by the capitalist. He would have found that the interest is here so high that, after settlement of all items, the worker ends up being the debtor, after not only having made restitution of the capitalist’s advance, but also having added his own labour to it free of charge. Historically, the form of industrial profit arises only after capital no longer appears alongside the independent worker. Profit thus appears originally determined by interest. But in the bourgeois economy, interest determined by profit, and only one of the latter’s parts. Hence profit must be large enough to allow of a part of it branching off as interest.

Historically, the inverse. Interest must have become so depressed that a part of the surplus gain could achieve independence as profit. There is a natural relation between wages and profit – necessary labour and surplus labour; but is there any between profit and interest, same [as] that which is determined by the competition between these two classes arranged under these different forms of revenues? But in order that this competition exist, the [existence of the] two classes, the division of the surplus value into profits and interest, is already presupposed. To examine capital in general is not a mere abstraction. If I regard the total capital of e.g. a nation as distinct from total wage labour (or, as distinct from landed property), or if I regard capital as the general economic basis of a class as distinct from another class, then I regard it in general. Just as if I regard man e.g. as physiologically distinct from the animals. The real difference between profit and interest exists as the difference between a moneyed class of capitalists and an industrial class of capitalists. But in order that two such classes may come to confront one another, their double existence presupposes a divergence within the surplus value posited by capital.

(Political economy has to do with the specific social forms of wealth or rather of the production of wealth. The material of wealth, whether subjective, like labour, or objective, like objects for the satisfaction of natural or historical needs, initially appears as common to all epochs of production. This material therefore appears initially as mere presupposition, lying quite outside the scope of political economy, and falls within its purview only when it is modified by the formal relations, or appears as modifying them. What it is customary to say about this in general terms is restricted to abstractions which had a historic value in the first tentative steps of political economy, when the forms still had to be laboriously peeled out of the material, and were, at the cost of great effort, fixed upon as a proper object of study. Later, they become leathery commonplaces, the more nauseating, the more they parade their scientific pretensions. This holds for everything which the German economists are in the habit of rattling off under the category ‘goods’.)

The important thing is that both interest and profit express relations of *capital.* As a particular form, interest-bearing capital stands opposite, not labour, but rather opposite profit-bearing capital. The relation in which on one side the worker still appears as independent, i.e. not as wage labourer, but on the other side his objective conditions already possess an independent existence alongside him, forming the property of a particular class of usurers, this relation necessarily develops in all modes of production resting more or less on exchange – with the development of merchant wealth or money wealth in antithesis to the particular and restricted forms of agricultural or handicraft wealth. The development of this mercantile wealth may itself be regarded as the development of exchange value and hence of circulation and of money relations in the former spheres. Of course, this relation shows us, on one side, the growing independence, the unbinding of the conditions of labour – which more and more come out of circulation and depend on it – from the worker's economic being. On the other side, the latter is not yet subsumed into the process of capital. The mode of production therefore does not yet undergo essential change. Where this relation repeats itself within the bourgeois economy, it does so in the backward branches of industry, or in such branches as still struggle against their extinction and absorption into the modern mode of production. The most odious exploitation of labour still takes place in them, without the relation of capital and labour here carrying within itself any basis whatever for the development of new forces of production, and the germ of newer historic forms. In the mode of production itself, capital still here appears materially subsumed under the individual workers or the family of workers – whether in a handicraft business or in small-scale agriculture. What takes place is exploitation by capital without the mode of production of capital. The rate of interest appears very high, because it includes profit and even a part of wages. This form of usury, in which capital does not seize possession of production, hence is capital only formally, presupposes the predominance of pre-bourgeois forms of production; but reproduces itself again in subordinate spheres within the bourgeois economy itself.

Second historic form of interest: Lending of capital to wealth which is engaged in consumption. Appears historically important here as itself a moment in the original rise of capital, in that the income (and often the land, too) of the landed proprietors accumulates and becomes capitalized in the pockets of the usurer. This is one of the processes by which circulating capital or capital in the form of money comes to be concentrated in a class independent of the landed proprietors.

The form of realized capital as well as of its realized surplus value is money. Profit (not only interest) thus expresses itself in money; because in that value is realized and measured.

The necessity of payments in money – not only of money for the purchase of commodities etc. – develops wherever exchange relations and money circulation take place. It is by no means necessary that exchange should be simultaneous. With money, the possibility is present that one party cedes his commodity and the other makes his payment only later. The need for money for this purpose (later developed in loans and discounts) a chief historic source of interest. This source does not concern us at all yet at this point; is to be looked at only along with credit relations.

Difference between *buying* (M–C) and *selling* (C–M): 'when I sell, I have (1) added the profit to the commodity and obtained it; (2) an article universally representative or convertible, money, for which, money being always saleable, I can always command every other commodity; the superior saleableness of money being the exact effect or natural consequence of the less saleableness of commodities ... With buying, different. If he buys to sell again or supply customers, whatever may be the probability, there is no absolute certainty of his selling at a remunerative price ... But not all buy so as to sell again, but rather for their own use or consumption' etc. (p. 117 seq. Corbet, Th. *An Inquiry into the Causes and Modes of the Wealth of Individuals,* London, 1841.)

Economist, 10 April [1858]: 'A parliamentary return moved for by Mr James Wilson, shows that the mint coined in 1857 gold to the value of £4,859,000, of which £364,000 was in half sovereigns. The silver coinage of the year amounted to £373,000, the cost of the metal used being £363,000 ... The total amount coined in the ten years ending the 31st of December, 1857, was £55,239,000 in gold, and 2,434,000 in silver ... The copper coinage last year amounted in value to £6,720 – the value of the copper being £3,492; of this 3,163 was in pence, 2,464 in half-pence, and 1,120 in farthings ... The total value of the copper coinage of the last ten years was £141,477, the copper of which it was composed being purchased for £73,503.'

'According to Thomas Culpeper (1641), Josiah Child (1670), Paterson (1694), Locke (1700), wealth depends on the self-enforced reduction of the interest rate of gold and silver. Accepted in England during nearly two centuries.' (Ganilh.)

[83] When Hume, in antithesis to Locke, developed the determination of the interest rate by the rate of profit, he already had before his eyes a far greater development of capital; even more so Bentham when, towards the end of the eighteenth century, he wrote his defence of usury. (From Henry VIII to Anne, statutory reduction of interest.)

‘In every country: (1) a producing class and (2) a monied class, which lives from the interest on its capital.’ (p. 110.) (J. St. Mill, *Some Unsettled Questions of Political Economy,* London, 1844.)

‘It is by frequent fluctuation in a month, and by pawning one article to relieve another, where a small sum is obtained, that the premium for money becomes so excessive. 240 licensed pawn-brokers in London and about 1450 in the country … The capital employed is estimated at about 1 million. Turned over at least three times annually … Each time on the average for 33 1/3% profit; so that the inferior orders of England pay 1 million annually for a temporary loan of one million, exclusive of what they lose by goods being forfeited.’ (p. 114.) (Vol. I. J. D. Tuckett, *A History of the Past and Present State of the Labouring Population* etc., London, 1846.)

How merchant takes the place of master

‘Some works cannot be operated on other than a large scale, e.g. porcelain making, glass making etc. Hence are never handicrafts. Already in the thirteenth and fourteenth centuries, some works, like weaving, were carried on on a large scale.’ (Poppe, p. 32.)

‘In earlier times all factories belonged to the crafts, and the *merchant* remained merely the distributor and promoter of the handicrafts. This was still most strictly observed in the manufacture of cloth and textiles. But, by and by, in many localities the merchants began to set themselves up as masters’ (of course without the old masters’ guild prejudices, traditions, relations to the journeymen), ‘and to take journeymen into their employ for day-wages.’ (Poppe. p. 92, Vol. 1. *Geschichte der Technologie,* Göttingen, 1807–11.) This was a chief reason why, in England, industry proper struck root and arose in non-incorporated cities.

Merchant wealth

Mercantile capital, or money as it presents itself as merchant wealth, is the first form of capital, i.e. of value which comes exclusively from circulation (from exchange), maintains, reproduces and increases itself within it, and thus the exclusive aim of this movement and activity is exchange value. There are two movements, to buy so as to sell, and to sell so as to buy; but the form M–C–C–M predominates. Money and its increase appear as the exclusive purpose of the operation. The merchant neither buys the commodity for his own needs, for the sake of its use value, nor does he sell it so as to e.g. pay off contracts written in money, or so as to obtain another commodity for his own needs. His direct aim is increase of value, and namely in its direct form as money. Mercantile wealth is, firstly, money as medium of exchange; money as the mediating movement of circulation; it exchanges commodity for money, money for commodity and vice versa. Money likewise appears here as an end-in-itself, but without therefore existing in its metallic existence. It is here the living transformation of value into the two forms of commodity and money: the indifference of value towards the particular form of use value which it assumes, and at the same time its metamorphosis into all of these forms, which appear, however, merely as disguises. Thus, while the action of commerce concentrates the movements of circulation, hence money as merchant wealth is in one respect the first existence of capital, still appears as such historically, this form appears on the other side as directly contradictory to the *concept of value.* To buy cheap and sell dear is the law of trade. *Hence not the exchange of equivalents, with which trade, rather, would be impossible as a particular way of gaining wealth.*

Nevertheless, money as trading wealth – as it appears in the most various forms of society and at the most various stages of the development of the forces of social production – is merely the mediating movement between two extremes, which it does not dominate, and presuppositions which it does not create.

A. Smith, Vol. II (ed. Garnier): 'The great *trade* of every civilized society is that which is established between the inhabitants of the town and those of the countryside ... it consists in the *exchange of the raw product* for the *manufactured product ...* either directly, or by the intervention of money.' (p.

403.) Trade always concentrates; production originally on a small scale. ‘The town is a continual fair or marketplace where the inhabitants of the countryside go to exchange their raw product for manufactured products. It is this trade which supplies the inhabitants of the town both with the material of their labour and with the means of their subsistence. The quantity of *manufactured goods* which they sell to the inhabitants of the countryside necessarily determines the quantity of materials and subsistence they buy.’ (p. 408 [409].)

So long as ‘means of subsistence and of pleasure’ the chief aim, use value predominates.

It is part of the concept of value that it maintains itself and increases only through exchange. But the existing value, initially, money.

‘This industry, whose aim was something beyond absolute necessity, established itself in the towns long before it could be commonly practised by the cultivators of the countryside.’ (p. 452.)

‘Although the inhabitants of a town ultimately draw their subsistence and all the means and materials of their industry from the countryside, yet those of a town lying near the shores of the sea or of a navigable river may draw them also from the farthest corners of the world, either in exchange for the manufactured product of their own industry, or by performing the service of carriers alternately between distant countries and exchanging the products of these countries among them. Thus a city may become very wealthy, while not only the land in its immediate environs, but also all lands where it trades, are poor. Each of these countries, taken separately, can offer it only a very small part of subsistence and for business; but all of these countries, taken collectively, can supply it with a great quantity of subsistence and a great variety of employment.’ (p. [452,] 453.) (Italian cities were the first in Europe to rise by trade; during the crusades – Venice, Genoa, Pisa – partly by the transport of people and always by that of the supplies which had to be delivered to them. These republics were, in a manner of speaking, the supply commissaries of these armies.) (loc. cit.)

Merchant wealth, as constantly engaged in exchange and exchanging for the sake of exchange value, is in fact living money.

‘The inhabitants of mercantile towns imported refined objects and luxury articles from wealthier countries at a high price, thus furnishing new food for the vanity of the great landed proprietors, who bought them with alacrity, by paying great quantities of the raw produce of their estates for them. Thus the commerce of a great part of Europe at this time consisted in exchange of the raw produce of one country for the manufactured produce of a country more advanced in industry.' (p. [454,] 455.) 'When this taste had become sufficiently general to create a considerable demand, the merchants sought, so as to save the costs of transport, to establish similar manufactures in their own country. This the origin of the first manufactures for distant markets.' Luxury manufactures, arisen out of foreign commerce, established by merchants (p. [456–] 458) (worked up foreign materials). Ad. Smith speaks of a second sort, which 'arose naturally and by itself through successive refinement of the crude and domestic employments'. Worked up home-grown materials. (p. 459.)

The trading peoples of antiquity like the gods of Epicurus in the spaces between the worlds, or rather like the Jews in the pores of Polish society. Most of the independent trading peoples or cities attained the magnificent development of their independence through the *carrying trade,* which rested on the barbarity of the producing peoples, between whom they played the role of money (the mediators).

In the preliminary stages of bourgeois society, trade dominates industry; in modern society, the opposite.

Trade will naturally react back to varying degrees upon the communities between which it is carried on. It will subjugate production more and more to exchange value; push direct use value more and more into the background; in that it makes subsistence more dependent on the sale than on the immediate use of the product. Dissolves the old relations. Thereby increases money circulation. First seizes hold of the overflow of production; little by little lays hands on the latter itself. However, the dissolving effect depends very much on the nature of the producing communities between which it operates. For example, hardly shook the old Indian communities and Asiatic relations generally. Fraud in exchange is the basis of trade such as it appears independently.

But capital arises only where trade has seized possession of production itself, and where the merchant becomes producer, or the producer mere merchant. Opposed to this, the medieval guild system, the caste system etc. But the rise of capital in its adequate form presupposes it as commercial capital, so that production is no longer for use, more or less mediated by money, but for wholesale trade.

Commercial wealth as an independent economic form and as the foundation of commercial cities and commercial peoples exists and has existed between peoples on the most diverse stages of economic development, and within the commercial city itself (e.g. the old Asian, the Greek, and the Italian etc. of the Middle Ages) production can continue on in the form of guilds etc.

Steuart. ‘Trade is an operation, by which the wealth, or work, either of individuals, or of societies, may be exchanged by a set of men called merchants, for an equivalent, proper for supplying every want, without any interruption to industry, or any check to consumption. *Industry* is the application to ingenious labour in a free man, in order to procure, by the *means of trade,* an equivalent, fit for supplying every want.’ (Vol. I, p. 166.)

‘While wants continue simple and few, a workman finds time enough to distribute all his work; when wants become more multiplied, men must work harder; *time becomes precious;* hence trade is introduced ... The merchant as mediator between workmen and consumers.’ (p. 171.)

The collection (of products) into a few hands is the introduction of trade. (loc. cit.) The consumer does not buy so as to sell again. If the merchant buys and sells solely with a view to a gain (p. 174) (i.e. for value). ‘The simplest of all trades is that which is executed by *bartering of the most necessary means of subsistence’* (between the surplus food of the farmers and the free hands). ‘Progress chiefly to be ascribed to the introduction of money.’ (p. 176.) As long as mutual needs are supplied by barter, there is not the least occasion for money. This the simplest combination. When needs have multiplied, bartering becomes more difficult: upon this, *money* is introduced. This is the common price of all things. A proper equivalent in the hands of those who want. This operation of buying and selling is somewhat more complex than the first. Thus (1) *barter;* (2) *sale;* (3) *commerce.* The merchant must intervene. What was earlier called wants is now represented by the consumer; industry by the manufacturer, money by the merchant. The merchant represents money by substituting credit in its place; and as money invented for the facilitation of barter, so the merchant, with credit, a new refinement upon the use of money.

This operation of buying and selling is now trade; it relieves both parts of the whole trouble of transportation and adjusting wants to needs, or wants to money; the merchant represents by turns the consumer, the manufacturer, and money. Towards the consumer he represents the totality of manufacturers, to the latter the totality of consumers, and to both classes his credit supplies the use of money. (p. 177, 178.) *Merchants are supposed to buy and sell not out of necessity, but rather with a view to profit.* (p. 203.)

'First the industrialist produces for others' not for his own use; these goods begin to be of use to him only from the moment he exchanges them away. They thus make trade and the art of exchange necessary. They are only appraised by their exchangeable value.' (p. 161.) (Sismondi, *Études sur l'économie politique,* Vol. II, Brussels, 1837.) Trade has robbed things, pieces of wealth, of their primitive character of usefulness: *it is the antithesis between their use value and their exchangeable value to which commerce has reduced all things.* (p. 162.) At the beginning, utility is the true measure of values; ... trade exists then, in the patriarchal state of society; but it has not entirely absorbed the society; it is practised only upon the surplus of each one's production, and not on what constitutes its existence. (p. 162, 163.) By contrast, the character of our economic progress is that *trade* has taken on the burden of the *distribution* of the totality of the annually produced wealth and it has consequently suppressed absolutely its character of use value, letting only that of exchangeable value remain. (163.) Before the introduction of trade ... the increase in the quantity of the product was a direct increase of wealth. Less significant at that time was the quantity of labour by means of which this useful thing was obtained ... And really, the thing demanded loses none of its usefulness even if no labour at all were needed to obtain it; grain and linen would not be less necessary to their owners ... even if they fell to them from heaven. This is without a doubt the true estimate of wealth, enjoyment, and usefulness. But from the moment when men ... made their subsistence dependent on the exchanges they could make, or on commerce, they were forced to adhere to a different estimation, to exchange value, to value which results not from usefulness but rather from *the relation between the needs of the whole society and the quantity of labour which was sufficient to satisfy this need,* or as well the quantity of labour which might satisfy it in the future. (p. 266, loc. cit.) In the estimation of values, which people endeavoured to measure with the introduction of currency, the concept of usefulness is quite displaced. It is *labour,* the exertion necessary to procure oneself the two things exchanged for one another, which has alone been regarded. (p. 267.)

Gilbart (J. W.): *The History and Principles of Banking,* London, 1834, has this to say about interest:

'That a man who borrows money with *the intention of making a profit on it,* should give a portion of the profit to the lender, is a self-evident principle of natural justice. A man makes a profit usually by means of traffic. But in the Middle Ages the population purely agricultural. And there, like under the feudal government, there can be only little traffic and hence little profit ... Hence the usury laws in the Middle Ages justified ... Furthermore: in an agricultural country a person seldom wants to borrow money except he be reduced to poverty or distress by misery.' (p. 163.) Henry VIII limited interest to 10%, James I to 8, Charles II to 6, Anne to 5. (164, 165.) In those days, the lenders were, if not legal, still actual monopolists, and thus it was necessary to place them under restraint like other monopolists. (p. 165.) In our time the rate of profit governs the rate of interest; in those days the rate of interest governed the rate of profit. If the money-lender burdened the merchant with a higher rate of interest, then the merchant had to put a higher rate of profit on his goods, hence a greater sum of money taken out of the pockets of the buyers so as to bring it into the pockets of the money-lenders. This additional price put on the goods made capital less able and less inclined to buy them. (p. 165.) (loc. cit.)

Commerce with equivalents impossible. Opdyke

'Under the rule of invariable equivalents *commerce* etc. would be impossible.' (G. Opdyke, *A Treatise on Political Economy,* New York, 1851, p. 67.)

'The positive limitation of quantity on this instrument' (i.e. paper money) 'would accomplish the only useful purpose that cost of production does in the other' (metal money). (loc. cit. 300.)

Principal and interest

Interest. ‘If a fixed sum of precious metal falls, then this no reason that a smaller quantity of money should be taken for its use, for if the principal worth less for the borrower, so the interest in the same measure less difficult for him to pay … In California 3% per month, 36% per annum because of the unsettled state … In Hindustan, where borrowing by Indian princes for *unproductive expenses,* in order to balance the losses of capital on the average, very high interest, 30%, *having no relation to profit* which might be gained in industrial operations.’ (*Economist,* 22 January 1853.) (The lender ‘here charges interest so high as to be sufficient to replace the principal in a short time, or at least as on the average of all his lending transactions, might serve to counterbalance his losses in particular instances, by the apparently exorbitant gains acquired in others.’ (loc. cit.))

The rate of interest depends: (1) on the rate of profit; (2) on the proportion in which the entire profit divided between lender and borrower. (loc. cit.)

Abundance or scarcity of the precious metals, the high or low scale of general prices prevailing, determines only whether a greater or less amount of money will be required in effecting the exchanges between borrowers and lenders, as well as every other species of exchange … Difference only, that a greater sum of money would be needed to represent and transfer capital lent … the relation between the sum paid for the use of capital and the capital expresses the rate of interest as measured in money. (loc. cit.)

Double Standard. Previously, in countries where gold and silver legal standard, silver circulated almost exclusively, because from 1800 to 1850 the tendency was for gold to become dearer than silver … The gold was somewhat risen against silver, bore a premium in France on its relation to silver as fixed in 1802 … so in the United States; … in India. (In the latter now silver standard, as in Holland etc.) … The circulation of the United States the first affected. Great import of gold from California, premium on silver in Europe … extensive shipment of silver coins and replacement by gold. The United States government struck silver coins as low as 1 dollar … Substitution of silver for gold in France. (*Economist,* 15 November 1851.) Let the ‘standard of value’ be what it will, ‘and let the current money represent *any* fixed portion of that standard, that may be determined upon, the two can only have a fixed and permanent value in relation to each other, by being convertible at the will of the holder.’ (*Economist.*) [84]

The only way in which any class of coins can command a premium is that no one is obliged to pay them, while every one is obliged to take them as a legal tender. (*Economist.*) [85]

No country may consequently have more than one standard (more than *one* standard of the measure of value); for this standard must be uniform and unchanging. No article has a uniform, unchanging value relative to another; it only has such with itself. A gold piece is always of the same value as another, of exactly the same fineness, the same weight, and the same value in the same place; but this cannot be said of gold *and* any other article, e.g. silver. (*Economist,* 1844.) [86]

The English £ somewhat less than 1/3 of its original value, the German florin = 1/6, Scotland before the union [reduced] its pound 1/36, to the French *livre* 1/74, the Spanish *maravedi* = less than 1/1,000, the Portuguese *re* still lower. (p. 13, Morrison.) [87]

Before the law of 1819, causes in existence in determinating the bullion price apart from the circulation of bank notes: (1) the more or less perfect condition of the coin. If the circulating metallic coin is debased below its standard weight, then the slightest turn of exchange causing a demand for exportation must raise the price of the uncoined bullion by at least the degradation of the coin. (2) penal laws which forbade the melting and exporting of coin, and permitted the traffic in bullion. With intensive demand for export, this gave latitude for variation of bullion price against coin even at times when paper completely convertible. In 1783, 1792, 1795, 1796 … 1816, the bullion price rose above the mint price, because the bank-creditors, in their anxiety to prepare for the resumption of cash payment, accepted gold considerably above the mint price. (Fullarton.) [88]

The standard may be for gold, without one ounce of gold circulating. (*Economist.*)

Under George III (1774) silver legal tender only for £25. And the bank, by statute, now paid only in gold. (Morrison.) Lord Liverpool (beginning of the nineteenth century) made silver and copper into purely representative coins. (loc. cit.) [89]

Dissolving effect of money. *Money a means of cutting up property*

Urquhart's nonsense about the standard of money: 'The value of gold is to be measured by itself; how can any substance be the measure of its own worth in other things? The worth of gold is to be established by its own *weight,* under a false denomination of that weight – and an *ounce* is to be worth so many *pounds* and fractions of pounds. This is – falsifying a *measure,* not establishing a *standard*!' (*Familiar Words*.) [90]

Ad. Smith calls labour the *real* and money the *nominal measure of value;* presents the former as the original. [91]

Value of money. J. St. Mill. 'If the quantity of goods sold is given, and the number of sales and resales of these goods, then the value of money depends on its quantity, together with the number of times that each piece of money changes hands in this process.' 'The quantity of money in circulation = the money value of all commodities sold, divided by the number which expresses the velocity of circulation.' 'If the amount of commodities and transactions be given, then the value of money is the inverse of its quantity multiplied by its velocity of circulation.' But all these statements to be understood only in the sense 'that we speak only of the quantity of money which really circulates and is factually exchanged for commodities'. 'The necessary quantity of money determined partly by its production costs, partly by the velocity of its circulation. If the velocity of circulation is given, then the costs of production are determinant; if the production costs are given, then the quantity of money depends on the velocity of circulation.' [92]

Money has no equivalent other than itself or commodities. Hence degrades everything. At the beginning of the fifteenth century in France even the sacred vessels of the church (chalices) etc. pawned to the Jews. (Augier.) [93]

Money not a direct object of consumption: the currency never becomes an object of consumption, always remains a commodity, never becomes a good. Has a direct intrinsic value only for society; an exchangeable one for each individual. Its material must therefore have value, but founded on an artificial need, must not be indispensable for human existence; for the whole quantity of it which is used as currency can never be employed individually; it must always circulate. (Storch.) [94]

John Gray: *The Social System. A Treatise on the Principle of Exchange,* Edinburgh, 1831.

'To sell for money ought at all times to be made as easy as to buy with money; production would then become the uniform and never failing cause of demand.' (16.) It is the quantity that can be sold at a profit, not the quantity that can be made, that is the present limit to production. (59.)

Money should be merely a *receipt,* an evidence that the holder of it has either contributed a certain value to the national stock of wealth, or that he has acquired a right to the said value from some one who has contributed to it ... Money should be nothing more or less than portable, transferable, divisible, and inimitable evidences of the existence of wealth in store. (63, 64.) *An estimated value being previously put upon produce,* let it be lodged in a bank, and drawn out again whenever it is required; merely stipulating, by common consent, that he who lodges any kind of property in the proposed National Bank may take out of it an equal value of whatever it may contain, instead of being obliged to draw out the selfsame thing that he put in ... The proposed national banker should receive and take charge of *every* description of valuable, and give back *any* description of valuable again. (loc. cit. 68.)

'If money,' says Gray, 'be of *equal value* with that which it represents, it ceases to be a *representative* at all. It is one of the chief desideratums in money, that the holder of it should be compelled at one time or other to present it for payment at the place 'from whence he received it. But if money be of the same *intrinsic value* as that which is given for it, no such necessity exists.' (74.)

'Depreciation of stock ... should form an item of national charge.' (p. [115,] 116.) 'The business of every country is to be conducted ... on a national capital.' (171.) 'All land to be transformed into national property.' (298.)

Gray (John), *Lectures on the nature and use of Money* (Edinburgh, 1848): 'Man collectively *should* know no limit to his physical means of enjoyment, save those of the exhaustion either of *his industry or* [of] *his productive powers:* whilst we, by the adoption of a monetary system, false in principle, and destructive in practice, have consented to restrict the amount of our physical means of *enjoyment to that precise quantity which can be profitably exchanged for a commodity, one of the least capable of multiplication by the exercise of human industry* of any upon the face of the earth.' (29.) What will be required for a good system, is (1) a bank system through whose operations the *national* relationship of supply and demand would be restored; (2) a *true* standard of value, instead of the existing fiction. (108.) (In this book the idea of the exchange-bank developed in still more detail and with preservation of the present mode of production.) 'There must be a minimum price of labour payable in standard money.' (p. 160.) Let us call e.g. the lowest rate of wages per week for 60–72 hours that may by law be given, 20s. or £1 standard. (161.) 'Shall we retain our *fictitious* standard of value, *gold,* and thus keep the productive resources of the country in bondage, or shall we resort to the *natural* standard of value, *labour,* and thereby set our productive resources free?' (p. 169.) The amount of this minimum wage being once fixed ... it should remain the same for ever. (174.) 'Merely let gold and silver take their proper place in the market beside butter and eggs and cloth and calico, and then the value of the precious metals will interest us no more than that of the diamond' etc. (182 [, 183].) No objection to make to gold and silver used *as instruments of exchange, ...* but only as *measures of value ...* In a short time one would see how many ounces of gold or silver were obtainable in London, Edinburgh or Dublin in exchange for a hundred pound standard note. (p. 188.)

Interest. As the class of rentiers increases, so also does that of lenders of capital, for they are one and the same. From this cause alone, interest must have had a tendency to fall in old countries. (201, 202 Ramsay.) 'It is probable that in all ages the precious metals cost more in their production than their value ever repaid.' (101, II. Jacob, W. *An Historical Enquiry into the Production and Consumption of Precious Metals,* London, 1831.)

Value of money. The value of all things, divided by the number of transactions of which they were the object, from product[ion] to the produc[er],

= the value of the *écus* used to buy them, divided by the number of times that these thalers have been transferred in the same space of time. (Sismondi, *Nouveaux Principes d'Économie Politique,* etc.)

The most formal development of the false theory of prices is by James Mill (quoted from the translation by J. T. Parisot, Paris, 1823. *Éléments d'Économie Politique*).

The chief passages in Mill are:

'*Value* of money = the proportion in which one exchanges it for other articles, or the quantity of money which one gives in exchange for a specific quantity of other things.' (p. 128.) This relation is determined by the *total quantity* of money existing in a country. If one supposes all the commodities of a country brought together on one side, and all the money on the other, then it is evident that in the exchange between both sides, the value of money, i.e. the quantity of the commodities for which it has been exchanged, entirely depends on its own quantity. (loc. cit.) The case is wholly the same in the actual state of things. The total mass of the commodities of a country is *not* exchanged *at once* for the total mass of the money, but rather the commodities are exchanged in portions, and often very small portions, at various periods in the course of the year. The same piece of money which has served today for one exchange may serve tomorrow for another. A part of the money is used for a very great number of exchanges, another part for a very small number, a third is stockpiled and serves for no exchange. Among these variations there will be a median rate, based on the number of exchanges for which each piece of money would be used if all had effected an equal number of exchanges. Let this rate be fixed at some convenient number, e.g. 10. If every piece of money in the country has served for 10 purchases, then it is the same as if the total number of pieces of money had increased tenfold, and each had served for only a single exchange. In this case the value of all commodities is equal to 10 times the value of the money etc. (p. 129, 130.) If, instead of each coin serving for 10 purchases a year, the total mass of money had increased tenfold, and the coin served for only one exchange, then it is evident that every increase of this mass would cause a relative diminution in the value of each of these coins taken separately. Since *it is supposed* that the mass of all commodities for which the money may exchange remains *the same,* therefore the value of the total mass of the money has become no greater after the increase of its quantity than before. If *one supposes* an increase of one-tenth, then the value of each of its parts, e.g. an ounce, must have diminished by one-tenth. (p. 130, 131.) ‘Thus, whatever may be the degree of the increase or decrease of the total mass of money, if the quantity of the other things remains the same, then this total mass and each of its parts experiences inversely a relative diminution or increase. It is clear that this thesis is of absolute truth. Whenever the *value of money* has experienced a rise or fall, and whenever the quantity of the commodities for which it could be exchanged, and the movement of circulation, remained the same, this change must have had as cause a relative increase or diminution of money, and can be ascribed to no other cause. If the mass of commodities decreases while the quantity of money remains the same, then it is as if the totality of money had increased, and vice versa. Similar changes are the result of every alteration in the *movement of circulation.* Every increase of the number of purchases produces the same effect as a total increase of money; a decrease of this number produces directly the *opposite* effect.’ (p. 131, 132.) If a portion of the annual product has not been exchanged at all, like that which the producers consume, or is not exchanged for money, then this portion must not be put on the account, because whatever does not exchange for money is in the same situation relative to money as if it did not exist. (p. 131, 132.) Whenever the increase or diminution of money can proceed freely, this quantity is governed by the value of the metal ... Gold and silver, however, are commodities, products ... The *costs of production* govern the value of gold and silver, like that of all other products. (p. 136.)

The insipidness of this reasoning is quite evident.

(1) *If one supposes* that the mass of commodities remains the same, and the velocity of circulation as well, but that nevertheless a great mass of gold or silver exchanges for this same mass of commodities (without the value, i.e. the amount of labour contained in gold and silver, having changed), then one supposes exactly what one wanted to prove, namely that the prices of commodities are determined by the quantity of the circulating medium and not vice versa.

(2) Mill concedes that the commodities not thrown into circulation do not

exist for money. It is equally clear that the money not thrown into circulation does not exist for the commodities. Thereby there exists no fixed relation between the value of money generally and the mass of it which enters into circulation. That the mass actually in circulation, divided by the number of its turnovers, is equal to the value of money is merely a tautological circumlocution for saying that the value of the commodity expressed in money is its price; since the money in circulation expresses the value of the commodities it circulates – it follows that the value of these commodities is determined by the *mass* of the circulating money.

(3) The confusion of Mill's view is clearly shown in his thesis that the value of money diminishes or increases with 'every alteration in the movement of circulation'. Whether one pound sterling circulates 1 time or 10 times a day, in each exchange it expresses an equivalent for the commodity, exchanges for the same value in commodities. Its own value remains the same in every exchange, and is hence altered neither by slower nor by rapid circulation. The mass of the circulating money is altered; but neither the value of the commodity, nor the value of the money. 'If it is said: a piece of cloth is worth £5, then it means: it possesses the value of 616,370 grains of standard gold. The reason assigned above may be paraphrased thus: "prices must fall because commodities are estimated as being worth so many ounces of gold; and the amount of gold in this country is diminished".' (Hubbard, J. G., *The Currency and the Country,* London, 1843, p. 44.)

(4) Mill at first supposes, in theory, that the whole mass of the money in a country is exchanged *at once* for the whole mass of the commodities which are to be found in it. Says, then, that this is so in reality, namely for the main reason that in practice just the opposite takes place, and only portions of money are exchanged for portions of commodities, the fewest payments arranged by payment on the spot – time bargains. Follows, therefore, that the total amount of transactions or purchases, made in a day, is entirely independent of the money circulating on this day, and that the mass of money circulating on any given day is not the cause but the effect of a mass of previous transactions, each of them wholly independent of the money supply at the time.

(5) Finally, Mill himself admits that with free circulation of money, and this is our only concern, the value of money is determined by its cost of production,

i.e., according to his own admission, by the labour time contained in it.

Monetary affairs. In Ricardo's pamphlet: *Proposals for an Economical and Secure Currency with Observations on the Profits of the Bank of England,* London, 1816, there is a passage where he makes a shambles of his whole viewpoint. It says, namely: 'The amount of notes in circulation depends ... on the amount required for the circulation of the country, and this is governed by the *value* of the standard, the amount of payments, and the economy applied to accomplish them'. (p. 8 loc. cit.)

Under Louis XIV, XV, XVI France still had, for its state taxes, taxes in kind levied on the rural people. (Augier.) [95]

Prices and mass of the circulating medium. Mere rise of prices not sufficient to create demand for additional currency. This only the case if production and consumption rise simultaneously. E.g. the price of grain rises, but its supply declines. Can thus be governed with the same quantity of currency ... but if rise of prices due to rising demand, new markets, enlarged scale of production, in a word, *rise of prices and of the general sum of transactions,* then it is necessary for the intervention of money to be multiplied in number and enlarged in magnitude. (Fullarton.) [96]

Trade governs money, not money trade. The servant of trade must follow the variations (in the prices) of the other commodities. (D'Avenant.) [97]

(Under the feudal kings, the few articles bought in mass quantities by the people fell so much that no gold or silver coin small enough to correspond to the daily requirement of the labourer ... current money thus like in ancient Rome only the inferior metals, copper, tin, iron.) (Jacob.) [98]

Jacob assumes that in this century, 2/3 of the gold and silver in Europe in other articles, utensils and ornament, not in coin. (In another passage he calculates the precious metal so used in Europe and America at £400 million.) [99]

Prices and mass of the circulating medium. Locke, *Spectator* (19 Oct. 1711), Hume, Montesquieu – their doctrine rests on three theses:

(1) Prices of commodities proportionate to the mass of money in the country; (2) the coin and current money of a country representative of all its labour and commodities, so that the more or less representation, the more or less quantity of the thing represented goes to the same quantity of it; (3) increase commodities, they become cheaper; increase money, they rise in their value. (Steuart.)

Markers (small copper money or silver money, *counters*) in antithesis to money of intrinsic worth. (loc. cit.)

Dissolving effect of money. Money a means of cutting up property (houses, other capital) into countless fragments and consuming it piece by piece through exchange. (Bray.) [100] (Without money, a mass of inexchangeable, inalienable objects.) 'As immobile and immutable things came into human commerce just as well as movable things made for exchange, money came into use as rule and measure (square), by which these things obtained appraisal and value.' (*Free Trade,* London, 1622.) [101]

Coin. The silver and copper markers are *representatives* of fractional parts of the pound sterling. (*Thus in a recent answer of the Lord of the Treasury*.)

Exchange value. F. Vidal says (likewise, Lauderdale) (and in certain respects Ricardo): 'The true social value is use or consumption value; exchangeable value serves only to characterize the *relative wealth* of each of the members of a society in comparison to the others.' (70. *De la Répartition des Richesses* etc., Paris, 1846.) On the other side, exchange value expresses the *social form* of value, while use value no economic form of it whatever, rather, merely the being of the product, etc. for mankind generally.

Two nations may exchange according to the law of profit in such a way that both gain, but one is always defrauded

<From the possibility that profit may be *less than* surplus value, hence that capital [may] exchange profitably without realizing itself in the strict sense, it

follows that not only individual capitalists, but also nations may continually exchange with one another, may even continually repeat the exchange on an ever-expanding scale, without for that reason necessarily gaining in equal degrees. One of the nations may continually appropriate for itself a part of the surplus labour of the other, giving back nothing for it in the exchange, except that the measure here [is] not as in the exchange between capitalist and worker.>

Money in the third role, as money. (Value for-itself, equivalent etc.) How important a role money still plays in this role – even in its immediate form – is revealed in time of crises, harvest failures etc., in short, whenever one nation must *suddenly* liquidate its account with another. Money in its immediate, metallic form then appears as the sole absolute *means of payment,* i.e. as the sole *counter-value,* acceptable equivalent. And consequently it pursues a moving course which directly contradicts that of all other commodities. Commodities are transported as means of payment etc. from the country where they are cheapest to the country where they are most expensive. Money, the opposite; in all periods where it brings out its specific inner nature, where, hence, money is called for, in antithesis to all other commodities, as value for-itself, as absolute equivalent, as general form of wealth, in the specific form of gold and silver – and such moments are always more or less moments of crisis, whether a general one, or a grain crisis – then gold and silver are always transmitted from the country where they are most expensive – i.e. where all commodity prices have fallen by the relatively greatest amount – to the country where they are cheapest, i.e. where the prices of commodities are relatively higher. ‘It is a singular anomaly in the economy of the exchanges, and one particularly deserving of remark, that … the course of transit (of gold between two nations equally employing gold as a circulating medium) is always *from* the country where for the moment the metal is *dearest,* to the country where it is *cheapest,* a rise of the market price of the metal to its highest limit in the home market, and a fall of the premium in the foreign market, being the certain results of that tendency to an efflux of gold which follows a depression of the exchanges.’ (J. Fullarton, *On the Regulation of Currencies* etc. 2nd ed., London, 1845, p. 119.)

Just as exchange as such begins where the communities end, and as money, as the measure, medium of exchange and general equivalent created by exchange itself, arose not in internal traffic but rather in that between different communities, peoples, etc., and there obtains its specific importance, so it was also κατʾ ἐξοχήν as medium of international payments – for the liquidation of international debts – that money cast its spell, in the sixteenth century, the period of bourgeois society's infancy, holding the exclusive interest of states and of incipient political economy. The important role which money (gold and silver) in this third form still plays in international traffic has only become fully clear and been again recognized by the economists since the regular succession of money crises in 1825, 1839, 1847 and 1857. The economists try to extricate themselves by pointing out that money is called for here not as medium of circulation, but as *capital.* This is correct. Only it should not be forgotten that capital is being called for in the specific form of gold and silver, and not in that of any other commodity. Gold and silver appear in the role of absolute medium of international payments, because they are money as value-for-itself, as independent equivalent. 'This, in fact, is not a question of *currency* but of *capital*.' (It is rather a question of money, not of currency, nor of capital, because it is not *capital* which is indifferent to the special form in which it exists, but value in the specific form of money which is requested) '... all those various causes which, in the existing condition of monetary affairs, are capable ... of directing the stream of bullion from one country to another' (i.e. giving origin to a *drain of bullion),* 'resolve themselves under a single head, namely the state of the balance of foreign payments, and the continually recurring necessity of transferring *capital'* (but *notabene!* capital in the form of money) 'from one country to another to discharge it. For example failure of crops ... Whether that capital is *transmitted in merchandise or in specie* is a point which in no way affects the nature of the transaction' *(affects it very materially!).* Further, war-expenditure. (The case of transmission of capital in order to place it out to greater advantage at interest does not concern us here; nor does that of a surplus quantity of foreign goods imported, which Mr Fullarton cites, although this case certainly belongs here if this surplus importation coincides with crises.) (Fullarton, loc. cit. 130, 131.) 'Gold is preferred for this transmission of capital' (but in cases of violent drains of bullion it is absolutely not a question of preference) 'only in those cases where it is likely to effect the payment more conveniently, promptly, or profitably, *than any other description of stock or capital.'* (Mr Fullarton falsely treats the transmission of gold or another form of capital as a matter of preference, whereas the question is precisely those cases when *gold* must be transmitted in the international trade, just as at the same time bills in the domestic trade must be acquitted in the legal money, and not in any substitute.) 'Gold and silver … can always be conveyed to the spot where it is wanted with precision and celerity, and may be counted upon to realize on its arrival nearly the exact sum required to be provided, rather than incur the hazard of sending it in tea, coffee, sugar, or indigo. *Gold and silver possess an infinite advantage over all other descriptions of merchandise for such occasions,* from the circumstance of their being universally in use as money. It is not in tea, coffee, sugar, or indigo that debts, whether foreign or domestic, are *usually contracted to be paid, but in coin;* and a remittance, therefore, either in the identical coin designated, or in bullion which can be promptly turned into that coin through the Mint or Market of the country to which it is sent, must always afford to the remitter the most certain, immediate, and accurate means of effecting this object, without risk of disappointment from the failure of demand or fluctuation of price.' (132, 133.) Thus he cites precisely its property of being money, general commodity of contracts, standard of values, and with the possibility of being immediately converted at liberty in medium of circulation. The English have the apt expression *currency* for money as medium of circulation (*Münze,* coin, does not correspond to this, because it is itself the medium of circulation in a particular form again) and *money* for it in its third attribute. But since they have not particularly developed the latter, they declare this money to be *capital,* although they are then in practice forced to distinguish again between this particular form of capital, and capital generally.

'Ricardo appears to have entertained very peculiar and extreme opinions as to the limited extent of the offices performed by gold and silver in the adjustment of foreign balances. Mr Ricardo had passed his life amid the controversies which grew out of the Restriction Act,' [102] and had accustomed himself so long to consider all the great fluctuations of exchange and of the price of gold as the result of the excessive issues of the Bank of England, that at one time he seemed scarcely willing to allow that such a thing could exist as an adverse balance of commercial payments … And so slight an account did he set on the functions performed by gold in such adjustments, as to have even anticipated that *drains* for *exportation* would cease altogether so soon as cash payments should be resumed, and the currency restored to the metallic level … (See *Ricardo's Evidence before the Lords' Committee of 1819 on the Bank of England,* p. 186.) … But since 1800, when paper quite displaced gold in England, our merchants did not really want it; for, owing to the unsettled state of continental Europe, and the increased consumption there of imported manufactures, in consequence of the interruption given to industry and to all domestic improvement by the incessant movement of invading armies, together with the complete monopoly of the colonial trade which England had obtained through her naval superiority, the export of commodities from Great Britain to the Continent continued greatly to exceed her imports from thence, so long as the intercourse remained open; and after that intercourse was interrupted by the Berlin and Milan decrees, the transactions of trade became much too insignificant to affect exchanges in one way or the other. It was the foreign military expenditures and the subsidies, and not the necessities of commerce, that contributed in so extraordinary a manner to derange the exchanges and enhance the price of bullion in the latter years of the war. The distinguished economists of that period, therefore, had few or no real opportunities of practically estimating the range of which foreign *commercial* balances are susceptible.' (Believed that with war and over-issue, the international transmission of bullion would cease.) 'Had Mr Ricardo lived to witness the drains of 1825 and 1839, he would no doubt have seen reason to alter his views.' (loc. cit. 133–6.)

Price is the *money value* of commodities. (Hubbard.) [103] Money has the quality of being always exchangeable for what it measures, and the quantity required for the purposes of exchange must vary, of course, according to the quantity of property to be exchanged. (100. J. W. Bosanquet. *Metallic, Paper, and Credit Currency* etc., London, 1842.) 'I am ready to admit that gold is a commodity in such general demand that it may always command a market, that it can always buy [all] other commodities; whereas, other commodities cannot always buy gold. The markets of the world are open to it as merchandise at less sacrifice upon an emergency than would attend an export of any other article, which might in quantity or kind be beyond the usual demand in the country to which it is sent.' (Th. Tooke. *An Enquiry into the Currency Principle* etc., 2nd ed., London, 1844, p. 10.) 'There must be a very considerable amount of the precious metals applicable and applied as the most convenient mode of adjustment of international balances, being a commodity more generally in demand, and less liable to fluctuations in market value than any other.' (p. 12, 13.)

(Causes, according to Fullarton, of the rise of bullion price above the mint price: 'Coin debased by wear to the extent of 3 or 4% below its standard weight; ... penal laws which prohibited the melting and exportation of the coin, while the traffic in the metal of which that coin was composed remained perfectly free. These causes themselves, however, acted only during periods of unfavourable rate of exchange ... [The market price of money] fell, however, from 1816 to 1821 always to the *bank price* of bullion, when the exchange in favour of England; never rose higher, when the exchange unfavourable, than to such a rate as would indemnify the melters of the coin for its degradation by wear and for the penal consequences of melting it, but rose no higher.' (Fullarton, see his book, p. 8, 9.) 'From 1819 to the present time, amid all the vicissitudes which the money has undergone during that eventful period, the market-price of gold has on no occasion risen above 78s. per oz., nor fallen below 77s. 6d., an extreme range of only 6 in the ounce. Nor would even that extent of fluctuation be now possible; for it was solely owing to the renewed deterioration of the coin that even so trivial a rise occurred as 1 1/2d. in the ounce, or about 1/6% above the Mint-price; and the fall to 77s. 6d. is entirely accounted for by the circumstance of the Bank having at one time thought proper to establish that rate as the limit for its purchases. Those circumstances, however, exist no longer. For many years the Bank has been in the practice of allowing 77s. 9d. for all the gold brought to it for coinage' (i.e. the bank pockets 1 1/2d. mintage, which the coin gives it free of charge); 'and as soon as the recoinage of sovereigns now in progress shall be completed, there will be an effectual bar, until the coin shall again become deteriorated, to any future fluctuation of the price of gold bullion in our market beyond the small fractional difference between 77s. 9d. allowed by the Bank, and the Mint-price of 77s. 10

1/2d.’ (loc. cit. p. 9, 10.)

Contradiction between money as measure and equivalent on one side and as medium of circulation. In the latter, abrasion, loss of metallic weight. Garnier already remarks that ‘if a somewhat worn *écu* were taken as being worth somewhat less than a quite new one, then circulation would be constantly hampered, and every payment would give rise to disputes.’ [104]

(The material designed for accumulation naturally sought for and chosen from the realm of *minerals.* Garnier.) [105]

‘It being obvious that the coinage, in the very nature of things, must be forever, unit by unit, falling under depreciation by the mere action of ordinary and unavoidable abrasion (to say nothing of the inducement which a very restoration of the coinage holds out to the whole legion of ‘players’ and ‘sweaters’), it is a physical impossibility at any time, even for a single day, utterly to exterminate light coins from circulation.’ (*The Currency Theory reviewed* etc. By a Banker in England. Edinburgh, 1845, p. 69.) This written December 1844 commenting upon the operation of the then recent proclamations respecting the light gold in circulation in a letter to *The Times.* (Hence difficulty: If the light money is refused, then all standards insecure. If it is accepted, then door is opened to fraud and the same result.) That is why he says, in regard to the above-cited proclamations: ‘The effect ... has virtually been to denounce the whole of the current gold coin as an unsafe and illegal medium for monetary transactions.’ (p. 68, 69, loc. cit.) ‘In English law, when a gold sovereign is more than 0.774 grains deficient in weight, it may no longer pass as current. No such law for silver money.’ (54. Wm H. Morrison, *Observations on the System of Metallic Currency Adopted in this Country,* London, 1837.)

Assertion by the currency people that the value of a currency depends on its quantity. (Fullarton, p. 13.) If the value of the currency is given, and prices and the mass of transactions likewise (as well as the velocity of circulation), then of course only a *specific quantity* can circulate. Given prices and the mass of transactions as well as the velocity of circulation, then this quantity depends exclusively on the *value* of the currency. Given this value and the velocity of circulation, it depends exclusively on prices and on the mass of transactions. In this way is the quantity determined. If, however, the money in circulation is representative money – mere value-symbols – then it depends on the standard they represent what quantity of them can circulate. From this it has been wrongly concluded that quantity alone determines its value. For example, paper chits representing pounds cannot circulate in the same quantity as those which represent shillings.

Profit-bearing capital is the real capital, value posited as simultaneously self-reproducing and multiplying, and as constantly self-equivalent presupposition, distinguished from itself as surplus value posited by itself. Interest-bearing capital is in turn the purely abstract form of profit-bearing capital.

Since capital is posited as profit-bearing, in accordance with its value (presupposing a specific stage of the force of production), the commodity – or the commodity posited in its form as money (in its corresponding form as independent value, or, as we may now say, as realized capital) – may enter into circulation as *capital;* it may become a commodity, *as capital.* In this case, it is capital lent out at interest. The form of its circulation – or of the exchange it undergoes – then appears as specifically distinct from that examined hitherto. We have seen that capital posits itself both in the role of the commodity and in the role of money; but this happens only in so far as both appear as moments of the circulation of capital, in which it alternately realizes itself. These are only its vanishing and constantly re-created modes of existence, moments of its life's process. But capital as capital, capital itself as commodity, has not itself become a moment of circulation. The commodity has not been sold as capital; nor money as capital. In a word, neither commodity nor money – and we need actually regard only the latter as the adequate form – have entered into circulation as *profit-bearing values.*

Maclaren says:

' "Mr Tooke, Mr Fullarton, and Mr Wilson consider money as possessing intrinsic value as a commodity, and exchanging with goods according to that value, and not merely in accordance with the supply of pieces at the time; and they suppose with Dr Smith that exports of bullion are made quite irrespective of the state of the currency, to discharge balances of international debt, and to pay for commodities such as corn, for which there is a sudden demand, and that they are taken from a fund which forms no part of the internal circulation, nor affects prices, but is set apart for these purposes … Difficulty in explaining in what manner the bullion they say is set apart for this purpose, and has no effect on prices, can escape the laws of supply and demand, and though existing in the shape of money lying unemployed and known for the making of purchases, is neither applied for that purpose nor affects prices by the possibility of its being so applied.” The reply to this is, that the stock of bullion in question represents surplus-capital, not surplus-income, and is not available, therefore, merely to increase the demand for commodities, except on condition of increasing also the supply. Capital in search of employment is not a pure addition to the demanding power of the community. It cannot be lost in the currency. If it tends to raise prices by a demand, it tends to lower them by a corresponding supply. Money, as the security for capital, is not a mere purchasing power – it purchases only in order to sell, and finally goes abroad in exchange for foreign commodities rather than disburse itself in merely adding to the currency at home. Money, as the security for capital, never comes into the market so as to be set off against commodities, because its purpose is to produce commodities; it is only the money which represents *consumption* that can finally affect prices.’ (*Economist,* 15 May ’58.) [106]

‘Mr Ricardo maintained that prices depend on the relative amount of the circulating medium and of commodities respectively, and that prices rise only through a depreciation of the currency, that is, from a too great abundance of it in proportion to commodities, that they fall either from a reduction in the amount of the currency, or from a relative increase in the stock of general commodities which it circulates. *All* the bullion and gold coin in the country is, according to Mr Ricardo, to be reckoned currency, and if this increases without a corresponding increase in commodities, the currency is depreciated, and it becomes profitable to export bullion rather than commodities. On the other hand, if a bad harvest or any other calamity cause a great destruction of commodities, without any corresponding change in the amount of the circulation, the currency, whose amount was proportioned to the estimated rather than to the suddenly reduced market of commodities, again becomes redundant or ‘depreciated’, and must be diminished by exportation before its value can be restored. According to this view of the circulation, which is at the root of Lord Overstone’s theory, the supply of circulating medium or currency is always capable of being indefinitely increased in amount, and diminishes in value according to that increase; and can be restored to its proper value only by exportation of the superabundant portion. Any issue, therefore, of paper money which might supply the gap caused by the exportation of the bullion, and so prevent the ‘natural’ fall of prices otherwise certain to ensue, is held by Mr Ricardo’s school to be an interference with the economical laws of price, and a departure from the principles which would necessarily regulate a purely metallic currency.’ (loc. cit.)

(1) Value

This section to be brought forward.

The first category in which bourgeois wealth presents itself is that of the *commodity.* The commodity itself appears as unity of two aspects. It is *use value,* i.e. object of the satisfaction of any system whatever of human needs. This is its material side, which the most disparate epochs of production may have in common, and whose examination therefore lies beyond political economy. Use value falls within the realm of political economy as soon as it becomes modified by the modern relations of production, or as it, in turn, intervenes to modify them. What it is customary to say about it in general terms, for the sake of good form, is confined to commonplaces which had a historic value in the first beginnings of the science, when the social forms of bourgeois production had still laboriously to be peeled out of the material, and, at great effort, to be established as independent objects of study. In fact, however, the use value of the commodity is a given presupposition – the material basis in which a specific economic relation presents itself. It is only this specific relation which stamps the use value as a commodity. Wheat, e.g., possesses the same use value, whether cultivated by slaves, serfs or free labourers. It would not lose its use value if it fell from the sky like snow. Now how does use value become transformed into commodity? Vehicle of *exchange value.* Although directly united in the commodity, use value and exchange value just as directly split apart. Not only does the exchange value not appear as determined by the use value, but rather, furthermore, the commodity only becomes a commodity, only realizes itself as exchange value, in so far as its owner does not relate to it as use value. He appropriates use values only through their sale [*Entäusserung*], their exchange for other commodities. Appropriation through sale is the fundamental form of the social system of production, of which exchange value appears as the simplest, most abstract expression. The use value of the commodity is presupposed, not for its owner, but rather for the society generally. (Just as a Manchester family of factory workers, where the children stand in the exchange relation towards their parents and pay them room and board, does not represent the traditional economic organization of the family, so is the system of modern private exchange not the spontaneous economy of societies. Exchange begins not between the individuals within a community, but rather at the point where the communities end – at their boundary, at the point of contact between different communities. Communal property has recently been rediscovered as a special Slavonic curiosity. But, in fact, India offers us a sample chart of the most diverse forms of such economic communities, more or less dissolved, but still completely recognizable; and a more thorough research into history uncovers it as the point of departure of all cultured peoples. The system of production founded on private exchange is, to begin with, the historic dissolution of this naturally arisen communism. However, a whole series of economic systems lies in turn between the modern world, where exchange value dominates production to its whole depth and extent, and the social formations whose foundation is already formed by the dissolution of communal property, without

[Here the manuscript breaks off.]

[BASTIAT AND CAREY][107]

Bastiat. Harmonies économiques. *2 édition Paris, 1851*

Foreword

The history of modern political economy ends with Ricardo and Sismondi: antitheses, one speaking English, the other French – just as it begins at the end of the seventeenth century with Petty and Boisguillebert. Subsequent political-economic literature loses its way, moving either towards eclectic, syncretistic compendia, such as e.g. the work of J. St. Mill, or into deeper elaboration of individual branches, such as e.g. Tooke's *History of Prices* and, in general, the newer English writings about circulation – the only branch in which real new discoveries have been made, since the works about colonization, landed property (in its various forms), population etc. actually differ from the older ones only in the greater completeness of their material – or the reproduction of old economic disputes for a wider public, and the practical solution of questions of the day, such as the writings on free trade and protection – or, finally, into tendentious exaggerations of the classical tendencies, a relation which e.g. Chalmers occupies toward Malthus and Gülich to Sismondi, as well as in certain respects the older writings of MacCulloch and Senior to Ricardo. It is altogether a literature of epigones; reproduction, greater elaboration of form, wider appropriation of material, exaggeration, popularization, synopsis, elaboration of details; lack of decisive leaps in the phases of development, incorporation of the inventory on one side, new growth at individual points on the other. The only exceptions seem to be the writings of Carey, the Yankee, and Bastiat, the Frenchman, the latter of whom confesses that he leans on the former. [108] Both grasp that the antithesis to political economy – namely socialism and communism – finds its theoretical presupposition in the works of classical political economy itself, especially in Ricardo, who must be regarded as its complete and final expression. Both of them therefore find it necessary to attack, as a misunderstanding, the theoretical expression which the bourgeois economy has achieved historically in modern economics, and to demonstrate the harmony of the relations of production at the points where the classical economists naïvely described this antagonism. Notwithstanding the altogether different, even contradictory national environment from within which each of them writes, they are driven to identical endeavours. Carey is the only original economist among the North Americans. Belongs to a country where bourgeois society did not develop on the foundation of the feudal system, but developed rather from itself; where this society appears not as the surviving result of a centuries-old movement, but rather as the starting-point of a new movement; where the state, in contrast to all earlier national formations, was from the beginning subordinate to bourgeois society, to its production, and never could make the pretence of being an end-in-itself; where, finally, bourgeois society itself, linking up the productive forces of an old world with the enormous natural terrain of a new one, has developed to hitherto unheard-of dimensions and with unheard-of freedom of movement, has far outstripped all previous work in the conquest of the forces of nature, and where, finally, even the antitheses of bourgeois society itself appear only as vanishing moments. That the relations of production within which this enormous new world has developed so quickly, so surprisingly and so happily should be regarded by Carey as the eternal, normal relations of social production and intercourse, that these should seem to him as hampered and damaged by the inherited barriers of the feudal period, in Europe, especially England, which actually represents Europe to him, and that the English economists should appear to him to give a distorted, falsified reflection, generalization of these relations, that they should seem to him to confuse accidental distortions of the latter with their intrinsic character – what could be more natural? American relations against English ones: to this his critique of the English theory of landed property, wages, population, class antitheses etc. may be reduced. In England, bourgeois society does not exist in pure form, not corresponding to its concept, not adequate to itself. How then could the English economists' concepts of bourgeois society be the true, undimmed expression of a reality, since that reality was unknown to them? In the last analysis, the disturbing effect which traditional influences, influences not arising from the womb of bourgeois society itself, exercise upon its *natural* relations reduces itself for Carey to the influence, to the excesses and interferences of the state in bourgeois society. It is in the nature of wages, e.g., to rise with the productivity of labour. If we find that reality contradicts this law, then, whether in Hindustan or in England, we have only to abstract from the influence of the government, taxes, monopolies etc. If the bourgeois relations are regarded in themselves, i.e. after deduction of state influences, they will indeed always confirm the harmonic laws of the bourgeois economy. The question to what extent these state influences, public debt, taxes etc., grow out of the bourgeois relations themselves – and hence, e.g. in England, in no way appear as results of feudalism, but rather as results of its dissolution and defeat, and in North America itself the power of the central government grows with the centralization of capital – is one which Carey naturally does not raise. While Carey thus brings the higher power to which bourgeois society is developed in North America to bear against the English economists, Bastiat brings to bear the lower power of bourgeois society in France, against the French socialists. You believe yourselves to be rebelling against the laws of bourgeois society, in a land where these laws were never allowed to realize themselves! You only know them in the stunted French form, and regard as their inherent form what is merely its French national distortion. Look across, at England. Here, in our own country, the task is to free bourgeois society from the fetters which the state imposes on it. You want to multiply these fetters. First work out the bourgeois relations in their pure form, and then we may talk again. (Bastiat has a point, in so far as in France, owing to its peculiar social formation, many a thing is considered socialism that counts in England as political economy.)

Carey, however, whose point of departure is the American emancipation of bourgeois society from the state, ends with the call for state intervention, so that the pure development of bourgeois relations is not disturbed by external forces, as in fact happened in America. He is a protectionist, while Bastiat is a freetrader. All over the world, the harmony of economic laws appears as disharmony, and even Carey himself is struck by the beginnings of this disharmony in the United States. What is the source of this strange phenomenon? Carey explains it with the destructive influence of England, with its striving for industrial monopoly, upon the world market. Originally, the English relations were distorted by the false theories of her economists, internally. Now, externally, as the commanding power of the world market, England distorts the harmony of economic relations in all the countries of the world. This disharmony is a real one, not one merely based on the subjective conceptions of the economists. What Russia is, politically, for Urquhart, England is, economically, for Carey. The harmony of economic relations rests, according to Carey, on the harmonious cooperation of town and countryside, industry and agriculture. Having dissolved this fundamental harmony in its own interior, England, by its competition, proceeds to destroy it throughout the world market, and is thus the destructive element of the general harmony. The only defence lies in protective tariffs – the forcible, national barricade against the destructive power of large-scale English industry. Hence, the state, which was at first branded the sole disturber of these *'harmonies économiques',* is now these harmonies' last refuge. On the one side, Carey here again articulates the specific national development of the United States, their antithesis to and competition with England. This takes place in the naïve form of suggesting to the United States that they destroy the industrialism propagated by England, so as, by protective tariffs, to develop the same more rapidly themselves. This naïveté apart, with Carey the harmony of the bourgeois relations of production ends with the most complete disharmony of these relations on the grandest terrain where they appear, the world market, and in their grandest development, as the relations of producing nations. All the relations which appear harmonious to him within specific national boundaries or, in addition, in the abstract form of general relations of bourgeois society – e.g. concentration of capital, division of labour, wage labour etc. – appear as disharmonious to him where they appear in their most developed form – in their world market form – as the internal relations which produce English domination on the world market, and which, as destructive influences, are the consequence of this domination. If patriarchal gives way to industrial production within a country, this is harmonious, and the process of dissolution which accompanies this development is conceived in its positive aspect alone. But it becomes disharmonious when large-scale English industry dissolves the patriarchal or petty-bourgeois or other lower stages of production in a foreign country. The concentration of capital within a country and the dissolving effect of this concentration present nothing but positive sides to him. But the monopoly of concentrated English capital and its dissolving effect on the smaller national capitals of other countries is disharmonious. What Carey has not grasped is that these world-market disharmonies are merely the ultimate adequate expressions of the disharmonies which have become fixed as abstract relations within the economic categories or which have a local existence on the smallest scale. No wonder, then, that he in turn forgets the positive content of these processes of dissolution – the only side he recognizes in the economic categories in their abstract form, or in the real relations within the specific countries from which they are abstracted – when he comes to their full appearance, the world market. Hence, where the economic relations confront him in their truth, i.e. in their universal reality, his principled optimism turns into a denunciatory, irritated pessimism. This contradiction forms the originality of his writings and gives them their significance. He is equally an American in his assertion of the harmony within bourgeois society, as in his assertion of the disharmony of the same relations in their world-market form. In Bastiat, none of this. The harmony of these relations is a world beyond, which begins just at the point where the boundaries of France end; which exists in England and America. This is merely the imaginary, ideal form of the un-French, the Anglo-American relations, not the real form such as he confronts it on his own land and soil. Hence, as with him the harmony in no way arises out of the abundance of living observation, but is rather the *flat*, stilted product of a thin, drawn, antithetical reflection, hence the only moment of reality with him is the demand that the French state should give up its economic boundaries. Carey sees the contradictions in the economic relations as soon as they appear on the world market as *English* relations. Bastiat, who merely imagines the harmony, begins to see its realization only at the point where France ceases, and where all nationally separate component parts of bourgeois society compete among one another liberated from the supervision of the state. This ultimate among his harmonies – and the presupposition of all his earlier, imaginary ones – is however itself in turn merely a postulate, which is supposed to be realized through free-trade legislation. Thus, while Carey, quite apart from the scientific value of his researches, has at least the merit of articulating in abstract form the large-scale American relations, and, what is more, of doing so in antithesis to the old world, the only real background in Bastiat would be the small scale of the French relations, which everywhere poke their long ears through his harmonies. Still, this meritorious contribution is superfluous, because the relations of so old a country are sufficiently known and least of all require to become known by so negative a detour. Carey is rich, therefore, in, so to speak, *bonafide* research in economic science, such as about credit, rent, etc. Bastiat is preoccupied merely with pacifying paraphrases of researches ending in contrasts; hypocrisy of contentment. Carey's generality is Yankee universality. France and China are equally close to him. Always the man who lives on the Pacific and the Atlantic. Bastiat's generality is to ignore all countries. As a genuine Yankee, Carey absorbs from all directions the massive material furnished him by the old world, not so as to recognize the inherent soul of this material, and thus to concede to it the right to its peculiar life, but rather so as to work it up for his purposes, as indifferent raw material, as inanimate documentation for his theses, abstracted from his Yankee standpoint. Hence his strayings and wanderings through all countries, massive and uncritical use of statistics, a catalogue-like erudition. Bastiat, by contrast, presents fantasy history, his abstractions sometimes in the form of arguments, another time in the form of supposed events, which however have never and nowhere happened, just as a theologian treats sin sometimes as the law of human existence, then at other times as the story of the fall from grace. Hence both are equally unhistorical and anti-historical. But the unhistoric moment in Carey is the contemporary historic principle of North America, while the unhistoric element in Bastiat is a mere reminiscence of the French eighteenth-century manner of generalizing. Hence Carey is formless and diffuse, Bastiat affected and formally-logical. The most he achieves is commonplaces, expressed paradoxically, ground and polished into facets. With Carey, a couple of general theses, advanced in schoolmasterly form. Following them, a shapeless material, compendium, as documentation – the substance of his theses in no way digested. With Bastiat, the only material – abstracting from a few local examples, or whimsically refashioned English trivia – consists in the general theses of the economists. Carey's chief antithesis, Ricardo, in short, the modern English economists; Bastiat's, the French socialists.

XIV. On Wages

The following are Bastiat's main theses: All men strive for constancy of income, *fixed revenue.* <Truly French example: (1) All men want to be civil servants or

make their sons civil servants. (p. 371.)> Wages are a fixed form of remuneration (p. 376) and hence a very perfect form of association, in whose original form 'the aleatory' predominates, in so far as 'all the associated' are subject to 'all the risks of the enterprise'. <If capital takes the risk on its own account, the remuneration of labour becomes established under the name *wages.* If labour wants to take the consequences, good and bad, then the remuneration of capital splits off and establishes itself under the name *interest* (382).> (On this juxtaposition, see further p. 382, 383.) However, while the aleatory originally predominates in the worker's condition, the stability of wage labour is not yet sufficiently secured. There is an 'intermediate degree which separates the aleatory from stability'. This last stage is reached by 'saving, during days of work, the means to provide for the needs of days of old age and illness'. (p. 388.) The final stage develops by means of 'mutual aid societies' (loc. cit.) and in the final instance by means of the 'workers' *retirement fund'.* (p. 393.) (As man began with the need to become a civil servant, so he ends with the satisfaction of drawing a pension.)

As to 1. Suppose everything Bastiat says about the fixity of wages to be correct. Then we would still not know the *proper character* of wages, its characteristic specificity, simply because wages are subsumed under the fixed revenues. One of its relations – which it has in common with other sources of income – would be emphasized. Nothing more. This would already be something, admittedly, for the advocate who wishes to plead the advantages of wage labour. It would still be nothing for the economist who wishes to understand the peculiarity of this relation in its entire scope. A one-sided characterization of a relation, of an economic form, so as to make it the object of panegyrics in contrast to the opposite form; this cheap practice of lawyers and apologists is what distinguishes the logician, Bastiat. Thus, in place of wages, put: fixed income. Is a fixed income not a good thing? Does not everyone love to count on a sure thing? Especially every petty-bourgeois, narrow-minded Frenchman? the 'ever-needy' man? Human bondage has been defended in the same way, perhaps on better grounds. The opposite could also be asserted, and has been asserted. Equate wages to non-fixedness, i.e. progression past a certain point. Who does not love to get ahead, instead of standing still? Can a relation be bad which makes possible an infinite bourgeois progress? Naturally, Bastiat himself in another passage asserts wages as non-fixedness. How else, apart from non-fixedness, would it be possible for the worker to stop working, to become a capitalist, as Bastiat wishes? Thus wage labour is good because it is fixedness; it is good because it is non-fixedness; it is good because it is neither one nor the other, but both at the same time. What relation is not good, if it is reduced to a one-sided characterization and the latter is regarded as position, not as negation? All opportunist chattering, all apologetics, all philistine sophistry rests on this sort of abstraction.

After this general preface, we come to Bastiat's actual construction. Only, be it noted in passing that his rural sharecropper, [109] this type who combines in himself the misfortune of the wage labourer with the bad luck of the small capitalist, might indeed consider himself fortunate if he were put on fixed wages. Proudhon's 'descriptive and philosophical history' hardly holds a candle to that of his opponent Bastiat. The original form of association, wherein all the associates share all the risks of chance, is followed, as a higher stage of association entered into voluntarily by both sides, by a form in which the worker's remuneration is fixed. We will not call attention here to the genius of a procedure which begins by presupposing a capitalist on one side and a worker on the other, so as then, afterwards, to let the relation of capital and wage labour arise between them by their mutual agreement.

The form of association in which the worker is exposed to all the chance risks of the business – in which all producers are equally exposed to these risks – and which immediately precedes the form of wages, where the remuneration of labour gains fixity, becomes stable, as thesis precedes antithesis – is, as Bastiat tells us, the state in which fishing, hunting and herding form the dominant forms of production and society. First the wandering fisherman, hunter, herdsman – and then the wage labourer. Where and when has this *historic* transition from the semi-savage state into the modern taken place? If at all, then only in the burlesque. In real history, wage labour arises out of the dissolution of slavery and serfdom – or of the decay of communal property, as with oriental and Slavonic peoples – and, in its adequate, epoch-making form, the form which takes possession of the entire social being of labour, out of the decline and fall of the guild economy, of the system of Estates, of labour and income in kind, of industry carried on as rural subsidiary occupation, of small-scale feudal agriculture etc. In all these real historic transitions, wage labour appears as the dissolution, the annihilation of relations in which labour was fixed on all sides, in its income, its content, its location, its scope etc. *Hence as negation of the stability of labour and of its remuneration.* The direct transition from the African's fetish to Voltaire's supreme being, or from the hunting gear of a North American savage to the capital of the Bank of England, is not so absurdly contrary to history as is the transition from Bastiat's fisherman to the wage labourer. (Furthermore, in all these developments there is no sign of voluntary changes arising from mutual agreement.) This construction – in which Bastiat dishonestly conjures up his flat abstraction in the form of a historic event – is quite of the same rank as the synthesis in which the English friendly societies and the savings banks appear as the last word of wage labour and as the suspension of all social antinomies.

Thus the historic character of wage labour is non-fixity: the opposite of Bastiat's construction. But how did he come at all to construe fixity as the all-compensating aspect of wage labour? What led him to the wish to present wage labour in this form historically in other forms of society and of association, as a higher form of the remuneration of labour?

All economists, when they come to discuss the prevailing relation of capital and wage labour, of profit and wages, and when they demonstrate to the worker that he has no legitimate claim to share in the risks of gain, when they wish to pacify him generally about his subordinate role *vis-à-vis* the capitalist, lay stress on pointing out to him that, in contrast to the capitalist, he possesses a certain fixity of income more or less independent of the great adventures of capital. Just as Don Quixote consoles Sancho Panza with the thought that, although of course he takes all the beatings, at least he is not required to be brave. Thus an attribute which the economists attach to wage labour in antithesis to profit is transformed by Bastiat into an attribute of wage labour in antithesis to earlier forms of labour, and as progress relative to the remuneration of labour in these earlier relationships. A commonplace which takes up the standpoint of the prevailing relation, which consoles one of its sides towards the other, is taken out of this relation by Mr Bastiat and turned into the historic foundation of this relation's origin. In the relation of wages to profit, wage labour to capital, say the economists, wages have the advantage of fixity. Mr Bastiat says this fixity, i.e. one of the aspects of the relation of wages to profit, is the historical foundation on which wage labour arose (or, is an attribute of wages in antithesis not to profit, but rather to the earlier forms of the remuneration of labour), hence on which profit, hence the whole relation arose likewise. Thus a truism about one facet of the relation of wages and profit is surreptitiously transformed for him into the historic basis of this whole relation. This happens because he is constantly preoccupied by reflections upon socialism, which latter is then dreamed to be everywhere the first form of association. This an example of the importance assumed in Bastiat's hands by the apologetic commonplaces which accompany the course of development in the economists' writings.

To return to the economists. Of what does this fixity of wages consist? Are wages immutably fixed? This would altogether contradict the law of demand and supply, the basis of the determination of wages. No economist denies the fluctuations, the rise and fall of wages. Or are wages independent of crises? Or of machines which make wage labour redundant? Or of divisions of labour, which displace it? To assert any of this would be heterodox, and it is not asserted. What is meant is that in a certain average, wages realize a fair average level, i.e. the minimum wage for the whole class, a concept so hateful to Bastiat, and that a certain average continuity of labour takes place, e.g. that wages may continue on even in cases where profit falls or momentarily disappears entirely. Now, what does this mean other than that, if wage labour is presupposed as the dominant form of labour, as the foundation of production, then the working class exists from wages, and that labour individually possesses, on the average, the fixity of working for wages? In other words, a tautology. Where capital and wage labour is the dominant relation of production, there exists an average continuity of wage labour, and, to that extent, a fixity of wages for the worker. Where wage labour exists, it exists. And this is regarded by Bastiat as its all-compensating attribute. Furthermore, that in the state of society where capital is developed, social production as a whole is more regular, continuous, all-sided – hence, also, the income of the elements employed in it 'more fixed' – than where capital, i.e. production, is not yet developed to this stage, is yet another tautology which is given with the concept of capital itself and of production resting on it. In other words: that the general presence of wage labour presupposes a higher development of the productive forces than in the stages preceding wage labour, who denies this? And what would lead the socialists to the idea of raising higher demands if they did not presuppose this higher development of the forces of social production, brought about by wage labour? The latter is rather the presupposition of their demands.

Note. The first form in which wages make their general appearance – military pay [*Sold*], which arises with the decline and fall of national armies and of citizens' militias. First, the citizens themselves are paid as soldiers. Soon after that, their place is taken by mercenaries who have ceased to be citizens.

(2) *(It is impossible to pursue this nonsense any further. We, therefore, drop Mr Bastiat.)*

Editorial Notes

Page numbers in these notes refer to the printed edition of this translation. ‘MELI’ refers to the German edition edited by the Marx-Engels-Lenin Institute.

Introduction

1. Utopias on the lines of Defoe’s *Robinson Crusoe*.

2. Sir James Steuart (1712–80), ‘the rational exponent of the Monetary and Mercantile System’ (Marx), an adherent of the Stuart cause who went into exile in 1745 and pursued economic studies on the Continent. Author of *An Inquiry into the Principles of Political Economy,* London, 1767 (2 vols), Dublin, 1770 (3 vols – the edition used by Marx).

3. *A political animal.*

4. Frédéric Bastiat (1801–50), French economist, and ‘modern bagman of Free Trade’ (Marx). A believer in *laissez-faire* and the natural harmony of interests between labour and capital; a fierce opponent of socialism in theory and in practice (as deputy in the Constituent and Legislative Assemblies of 1848 to 1851).

5. Henry Charles Carey (1793–1879), American economist, opponent of Ricardian pessimism (‘Carey, who does not understand Ricardo’ – Marx), believed in state intervention to establish harmony between the interests of labour and of capital, and in the tendency of real wages to rise.

6. Of a commonplace (mind). Marx refers here to Bastiat’s *Harmonies économiques,* Paris, 1851, pp. 16–19, and Carey’s *Principles of Political Economy,* Pt I, Philadelphia, 1837, pp. 7–8.

7. John Stuart Mill (1806–73), English political theorist and economist; radical in politics, confusedly and eclectically Ricardian in economics. His *Principles of Political Economy,* London, 1848, begin in Bk I, Ch. 1, with the analysis of production.

8. *MEW* XIII omits ‘more’.

9. *MEW* XIII substitutes ‘in consumption’.

10. *MEW* XIII substitutes ‘products’.

11. ‘Determination is negation’, i.e., given the undifferentiated self-identity of the universal world substance, to attempt to introduce particular determinations is to negate this self-identity. (Spinoza, *Letters*, No. 50, to J. Jelles, 2 June 1674.)

12. [Translator advised this note should be removed.]

13. ‘Potentially’. Cf. Aristotle, *Metaphysics* Bk VIII, Ch. 6, 2.

14. The manuscript has: ‘for the product is production not only as … ‘. *MEW* XIII substitutes: ‘for the product is a product not as … ‘.

15. The manuscript has ‘for production’.

16. Jean-Baptiste Say (1767–1832), ‘the inane Say’, who ‘superficially condensed political economy into a textbook’ (Marx), a businessman who popularized and vulgarized the doctrines of Adam Smith in his *Traité d’économie politique*, Paris, 1803.

17. Heinrich Friedrich Storch (1766–1835), Professor of Political Economy in the Russian Academy of Sciences at St Petersburg. Say issued Storch’s work *Cours d’économie politique* with critical notes in 1823; he attacked Say’s interpretation of his views in *Considérations sur la nature du revenu national*, Paris, 1824, pp. 144–59.

18. David Ricardo, *On the Principles of Political Economy and Taxation*, 3rd edn, London, 1821, preface, p.v.

19. Marx considered that the Monetary System, as defined here, covered economists from the sixteenth century to the Physiocrats. However, within the Monetary System there arose what he calls here the ‘commercial, or

manufacture system' but elsewhere the Mercantile System (known to economics textbooks as Mercantilism). He distinguishes between the two systems on pp. 327–8, but his normal practice is to link them together, since 'the Mercantile System is merely a variant of the Monetary System' (A *Contribution to the Critique of Political Economy,* London, 1971, p. 158).

20. 'Potentially'. Cf. Aristotle, *Metaphysics* Bk VIII, Ch. 6, 2.

21. Pierre Joseph Proudhon, *Système des contradictions économiques ou philosophie de la misère,* Paris, 1846, Vol. I, p. 146.

22. *Capital* III (International Publishers edn), p. 110.

NOTEBOOK I: The Chapter on Money

1. Alfred Darimon (1819–1902), a follower of Proudhon. He edited Proudhonist newspapers in 1848, wrote on financial questions in the 1850s and was a democratic opponent of Napoleon III until 1864 when he went over to the Bonapartists.

2. In French in the original. Throughout this edition, passages in French, Italian and Spanish have been translated in the main body of the text; English has been left; Greek and Latin have been left in the text and translated in the notes.

3. Should read: ‘ … while the amount of securities decreases by 12,159,388; i.e. the decline of securities exceeds the decline of metal … ’. The correction of these and similar errors would in no way touch the substance of Marx’s conclusions concerning Darimon’s statistical ideas.

4. Isaac Péreire (1806–80), French banker and railway king who, together with his brother Émile, founded the Crédit Mobilier in 1852. A close associate of Napoleon III.

5. Michel Chevalier (1806–79), follower of Saint-Simon up to 1833; later Bonapartist. From 1850 he was Professor of Political Economy at the Collège de France, and a supporter in the 1850s of Bonaparte’s move towards free trade.

6. Ricardo’s pamphlet, *Proposals for an Economical and Secure Currency,* London, 1816.

7. A reference to the period during which the Bank Restriction Act was in operation (1797–1819).

8. A play on the two meanings of the French word *‘espèces’*: (1) sorts; (2) specie.

9. The Currency Act of 1844, which stringently limited the number of banknotes the country banks could issue, and also limited the fiduciary issue of the Bank of England to £14,000,000; any further issue had to be backed by coin or bullion.

10. Émile de Girardin (1806–81), French journalist, who edited *La Presse* from 1830 to 1857 and wrote the introduction to Darimon's book. A politician entirely lacking in scruples, he was a moderate republican in 1848, a Montagnard deputy to the Legislative Assembly in 1850 and a Bonapartist in 1852.

11. Potentially. Cf. Aristotle, *Metaphysics,* Bk VIII, Ch. 6, 2.

12. John Francis Bray (1809–95), economic pamphleteer and political activist in the England of the 1830s. In 1837 he became treasurer of the Leeds Working Men's Association. He advocated utopian socialist ideas in the pamphlet *Labour's Wrongs and Labour's Remedy,* Leeds, 1839, and was described by Marx as an 'English Communist' (*The Poverty of Philosophy,* Moscow, 1966, p. 60).

13. John Gray (1799–1850), economic pamphleteer and utopian socialist, author of *The Social System,* Edinburgh, 1831, and *Lectures on the Nature and Use of Money,* Edinburgh, 1848.

14. See below, pp. 153–60.

15. Hegel, *Science of Logic,* tr. A. V. Miller, London, 1969, p. 416.

16. Cf. Marx, *The Poverty of Philosophy,* pp. 52–68.

17. *Kaufmannsstand:* This refers above all to the merchants of the sixteenth and seventeenth centuries, who formed an 'estate' rather than a 'class'.

18. The following two paragraphs are directed specifically against the scheme outlined by John Gray in *The Social System,* pp. 62–86.

19. This note refers to an unknown manuscript by Marx, which must be older than his work of 1851 on ‘The Completed Money System’. Possibly it refers to one of the missing parts of the manuscript of 1845–7 on the ‘Critique of Politics and Political Economy’, fragments of which are reprinted in *Marx-Engels Gesamtausgabe* (MEGA) 1/3, pp. 33–172, 437–583 and 592–6. The 1851 manuscript,’The Completed Money System’, is not extant in full, and remains unpublished. [MELI note.]

20. This note refers to an unknown manuscript by Marx, which must be older than his work of 1851 on ‘The Completed Money System’. Possibly it refers to one of the missing parts of the manuscript of 1845–7 on the ‘Critique of Politics and Political Economy’, fragments of which are reprinted in *Marx-Engels Gesamtausgabe* (MEGA) 1/3, pp. 33–172, 437–583 and 592–6. The 1851 manuscript,’The Completed Money System’, is not extant in full, and remains unpublished. [MELI note.]

21. Atistotle, *Nicomachean Ethics,* Bk V, Ch. 5, para. 14.

22. This is directed against the doctrines of the Romantic reaction, as put forward by such people as Adam Müller (*Die Elemente der Staatskunst,* Berlin, 1809) and Thomas Carlyle (*Chartism,* London, 1840).

23. Menenius Agrippa (c. 530–493 B.C.) was a Roman patrician who is said to have persuaded the plebeians to return to Rome by comparing the patricians to the stomach and the plebeians to the limbs without which the stomach could not survive.

24. ‘ … Thou visible God! / That solder’st close impossibilities, / And mak’st them kiss! … ’ (*Timon of Athens,* Act 4, Scene 3).

25. ‘that accursed hunger for gold’ (Virgil, *Aeneid,* Bk 3, line 57).

26. *par excellence.*

65. See above, p. 146; money is ‘(3) representative of commodities (hence object of contracts)’, and see below section c, ‘money as material representative of wealth’, p. 203.

66. Steuart, *An Inquiry,* Vol. I, pp. 395–6.

67. F.-L.-A. Ferrier, *Du gouvernement considéré dans ses rapports avec le commerce,* Paris, 1805, p. 35. Ferrier (1777–1861) was a high French customs official who both operated and wrote in favour of Napoleon I’s protective system.

68. Louis Say (1774–1840), brother of Jean-Baptiste Say, issued a number of economic pamphlets criticizing the latter’s opinions. The reference here is to *Principales Causes de la richesse ou de la misère des peuples et des particuliers,* Paris, 1818, pp. 31–2.

69. Adam Smith, *Wealth of Nations,* Vol. II, Bk 2, pp. 270–77.

70. Edward Solly, *The Present Distress in Relation to the Theory of Money,* London, 1830, p. 5.

71. James Maitland, Earl of Lauderdale (1759–1839), Whig, then Tory, politician, author of economic works attacking Smith’s distinction between productive and unproductive labour. Marx refers here to the French translation of one of his books, entitled *Recherches sur la nature et l’origine de la richesse publique, et sur les moyens et les causes qui concourent à son accroissement,* Paris, 1808, p. 140.

72. James Taylor, *A View to the Money System of England, from the Conquest; with Proposals for Establishing a Secure and Equitable Credit Currency,* London, 1828, pp. 18–19.

73. Sismondi, *Études,* Vol. II, p. 278.

74. ibid., p. 300.

75. ‘The epitome of all things’ (Boisguillebert, *Dissertation,* p. 399).

NOTEBOOK II: The Chapter on Money (continuation)

1. ‘that accursed hunger for gold’ (Virgil, *Aeneid,* Bk 3, line 57).

2. The term *Gemeinwesen* also carries the nuances ‘common essence’, ‘common system’ and ‘common being’.

3. Steuart, *An Inquiry,* Vol. I, p. 327.

4. T. R. Malthus, *Principles of Political Economy,* London, 1836, p. 391.

5. Edward Misselden (seventeenth-century Mercantilist writer, active in the Merchant Adventurers’ Company, d. 1654), *Free Trade, or the Meanes to Make Trade Flourish,* London, 1622, pp. 19–24.

6. German: *Akkumulation.* But Marx presumably intended this word to have the sense *Anhäufung* (piling-up), as on the previous page, rather than the more technical economic sense he usually gives to the word.

7. Jacob, *An Historical Inquiry,* Vol. II, pp. 271–323.

8. Petty, *Political Arithmetick,* pp. 178–9.

9. Misselden, *Free Trade,* pp. 7, 12–13.

10. The notes on Boisguillebert are in an unnumbered excerpt-book compiled in June and July 1845 and printed in *MEGA*, 1/3, pp. 568–79. Marx discussed Boisguillebert’s polemic against the power of money in *A Contribution to the Critique of Political Economy*, London, 1971, pp. 54–5 and 124–6.

11. Nassau Senior, *Principes fondamentaux de l’économie politique, tirés de leçons édites et inédites,* Paris, 1836, pp. 116–17. (This is the translation by J. Arrivabene of Senior’s *Outline of the Science of Political Economy,* London, 1836). Senior himself (1790–1864) was an English political economist, a member of numerous mid-nineteenth-century government commissions, Professor of Political Economy in Oxford from 1847 to 1852, and noted for his two theories, that the profit of capital is the product of the last hour of the

working day, and that the accumulation of capital results from the abstinence of the capitalist from consumption.

12. Samuel Bailey (1791–1870, successful Sheffield businessman, ‘coarse practical bourgeois’ (Marx), and author of several economic pamphlets against Ricardo’s theory of value), *Money and its Vicissitudes in Value; as They Affect National Industry and Pecuniary Contracts; with a Postscript on Joint-Stock Banks,* published anonymously, London, 1837, p. 3.

13. Storch, *Cours d’économie politique,* Vol. II, p. 135.

14. Bailey, *Money and its Vicissitudes,* pp. 9–11.

15. Piercy Ravenstone, *Thoughts on the Funding System and its Effects* London, 1824, p. 20.

16. ‘These have one mind, and shall give their power and strength unto the beast’ (Revelation xvii, 13); ‘And that no man might buy or sell, save that he had the mark, or the name of the beast, or the number of his name’ (Revelation xiii, 17).

17. Storch, *Cours d’économie politique*, Vol. I, pp. 72–3.

NOTEBOOK II: The Chapter on Capital

18. The first few pages of the Chapter on Capital (pp. 239–50) were entitled by Marx ‘Chapter on Money as Capital’.

19. Charles Ganilh (1758–1836, French neo-Mercantilist economist, an advocate of the Napoleonic Continental System), *Des systèmes d’économie politique, de leurs inconvéniences, de leurs avantages, et de la doctrine la plus favorable aux progrès de la richesse des nations,* Paris, 1809. Vol. II. pp. 64–5.

20. Say, *Traité d’économie politique*, Vol. II, pp. 480–82.

21. *Sein für andres* is a basic concept of Hegel’s logic, described in the *Science of Logic* (p. 119 of the translation by A. V. Miller, London, 1969) as ‘a negation of the simple relation of being to itself which is supposed to be determinate being’. However, it is paired, not with *Sein für sich*, but with *Sein in sich* (being in itself, described as ‘something returned into itself out of the being for other’). In any case, it is difficult to detect any relation between Marx’s use of *Sein für andres* and Hegel’s use. The situation is different with the concept of *Sein für sich*, since Hegel described being for self in the *Lesser Logic* (p. 179 of the translation by W. Wallace, Oxford, 1892) in the following way: ‘Being for self is a self-subsistent, the One’, and added ‘The readiest instance of being for self is found in the “I”.’ This comes close to Marx’s ‘each individual ... as an end in himself’.

22. *Institutes*, Bk II, Title IX, para. 3 ‘A slave, who is in the power of another person, can have nothing of his own’ (*The Institutes of Justinian*, tr. J. B. Moyle, Oxford, 1906, p. 58).

23. See Marx’s critique of Proudhon’s doctrine of exchange value in *Poverty of Philosophy*, pp. 37–8.

24. The socialist opponents of Bastiat, in particular Proudhon. This passage is in fact a critique of the discussion between Bastiat and Proudhon, printed as F. Bastiat et P.-J. Proudhon, *Gratuité du crédit*, Paris, 1850, pp. 1–20, 32–47 and

285–6.

25. Say, *Traité d’économie politique*, Vol. II, pp. 428–30 and 478–80.

26. The German text has here ‘the other’, but since the reference back is to ‘landed property itself’ this has been replaced with ‘the latter’.

27. The German reads ‘as’, the sense seems to require ‘the’.

28. Cf. Hegel, *Science of Logic* (tr. A. V. Miller), p. 71: ‘That into which the movement returns as into its *ground* is (also) *result.*’

29. Adam Smith, *Wealth of Nations*, Vol. II, pp. 355–6.

30. The reference is to Marx’s own excerpt-book; the quotation is from Ganilh, *Des systèmes d’économie politique*, Vol. II, pp. 11–12.

31. Cf. Hegel, *Science of Logic*, pp. 106–8, 129–31.

32. The reference is to Marx’s own excerpt-book; the quotation is from Say, *Traité d’économie politique,* Vol. II, p. 185.

33. Sismondi, *Nouveaux Principes d’économie politique*, Paris, 1827, Vol. I, p. 89.

34. Marx used brackets (shown here by < and >) to indicate a digression.

35. Bastiat et Proudhon, *Gratuité du crédit*, p. 250.

36. ibid., pp. 177–80.

37. Constituted value is ‘*valeur faite*’; most perfect value is ‘valeur la plus parfaite’, ibid., p. 183.

38. For Ricardo’s discussion of the effects of difficulties of cultivation on rent, see *On the Principles of Political Economy,* pp 55–75.

39. Say, *Traité d’économie politique*, Vol. I, pp.2–6.

40. The ‘Misère’: Proudhon’s *Système des contradictions économiques, ou philosophie de la misère.* His doctrine of exchange value is put forward in Vol. I, pp 39–50.

41. See above, pp. 260–61.

42. ‘The epitome of all things’ (Boisguillebert, *Dissertation,* p. 399).

43. Storch, *Cours d’économie politique*, Vol. I, p. 154.

44. As in Adam Smith, *Wealth of Nations*, Vol. I, pp. 131–2.

45. Adam Smith, *Wealth of Nations*, Vol. II, pp. 355–85.

46. Storch’s views in *Considérations*, pp. 38–50; Senior’s in *Principes fondamentaux*, pp. 284–308.

47. Steuart, *An Inquiry*, Vol. I, p. 45.

48. Edward Gibbon Wakefield (1796–1862) was an English diplomat and economist, who put forward his views on the colonies in *A View of the Art of Colonization, with Present Reference to the British Empire,* London, 1849. He proposed that the government should reserve land in the colonies and put a higher price on it than prevailed in the open market.

49. Cf. Adam Smith, *Wealth of Nations*, Vol. I, pp. 104–5.

50. A reference to the abstinence theory advanced by Nassau Senior (*Principes fondamentaux*, pp. 307–8).

51. As in Charles Babbage, *Traité sur l’économie des machines et des manufactures.* Traduit de l’anglais sur la troisième édition, Paris, 1833, pp. 329–51.

52. Simon Linguet, (1736–94) was a French lawyer and historian, a conservative critic of the Enlightenment and of the economics of the Physiocrats, an opponent of the French Revolution. He was guillotined during the Terror. The reference here is to his book *Théorie des lois civiles, ou principes*

fondamentaux de la société, published anonymously in London, 1767, Vol. II, pp. 462–8.

53. The manuscript breaks off here, and the following page (page 29) is missing. Marx noted its contents as follows: ‘Capital a merely objective power *vis-à-vis* the worker. Without personal value. Distinction from the performance of service. Purpose of the worker in the exchange with capital – consumption. Must always begin anew. *Labour* as the *capital* of the *worker*’ (*Grundrisse* (MELI), p. 953).

NOTEBOOK III: The Chapter on Capital (continuation)

1. This is the continuation from the missing final page of the previous notebook. The first seven pages of the present (third) notebook are taken up by the section ‘Bastiat and Carey’ (see pp. 883–93), which was written in July 1857. The present text begins, then, on the eighth page of the third notebook, which carries the date *‘29th, 30th November, December’* in Marx’s hand. See *Grundrisse* (MELI), pp. 200 n., 842 n.

2. Cf. Hegel, *Philosophy of Right*, para. 67: ‘I can give to someone else the use of my abilities for a restricted period … but by alienating the whole of my time I would be making the substance of my being into another’s property.’

3. As in P. Gaskell, *Artisans and Machinery,* London, 1836, pp. 261–2.

4. Potentially.

5. Antoine Cherbuliez (1797–1869, Swiss lawyer and economist, follower of Sismondi, although he added some elements of Ricardian theory), *Richesse ou pauvreté: Exposition des causes et des effets de la distribution actuelle des richesses sociales*, Paris, 1841, p. 16.

6. Cf. Hegel, *Science of Logic*, p. 753: ‘The third relation, mechanism … is a sublating (*aufheben*) of the means, of the object already posited as sublated, and is therefore a second sublating and a reflection-into-self.’

7. For example John Gray, *The Social System*, p. 36, and J. F. Bray, *Labour’s Wrongs*, pp. 157–76.

8. See below, pp. 316–18 and pp. 461–71.

9. See below, pp. 310–12.

10. Adam Smith, *Wealth of Nations*, Vol. II, pp. 355–85.

11. Senior, *Principes fondamentaux*, pp. 197–206.

12. Malthus, *Principles of Political Economy*, p. 47, footnote by the editor,

William Otter, Bp of Chichester.

13. Sismondi, *Nouveaux Principes*, Vol. I, p. 90.

14. ibid., p. 105.

15. Cherbuliez, *Richesse ou pauvreté*, pp. 58, 64.

16. For example John Gray, *The Social System*, p. 36, and J. F. Bray, *Labour's Wrongs*, pp. 157–76.

17. In Ricardo: *On the Principles of Political Economy*, pp. 320–37. In Sismondi: *Études*, Vol. I, p. 22.

18. The MELI edition gives *lassen* (let, leave) rather than *fassen* (grasp, conceive, formulate); this is almost certainly either a misprint (the first of two on that page) or a misreading.

19. Say, *Traité d'économie politique*, Vol. II, p. 429 n.

20. Sismondi, *Études*, Vol. II, p. 273.

21. This is Adam Smith's phrase, not Ricardo's (Smith, *Wealth of Nations,* Vol. II, p. 355).

22. Say, *Traité d'économie politique*, Vol II, p. 425.

23. 'Capital has value, labour produces.' Proudhon, *Système des contradictions économiques,* Vol. I, p. 61.

24. Cf. Hegel, *Science of Logic*, p. 633: 'In the judgement the subject is determined by the predicate … the predicate is determined in the subject.'

25. 'The act of producing'.

26. Incidental 'false' expenses of production: the category into which the political economists from Adam Smith onwards relegated the cost of maintaining necessary but unproductive workers, e.g. soldiers, doctors etc.

27. Bastiat et Proudhon, *Gratuité du credit*, p. 180.

28. Cf. Hegel, *Science of Logic*, pp. 717–18; ‘The action passes over into *rest*. It shows itself to be a merely *superficial*, transient alteration in the self-enclosed indifferent totality of the object. This return constitutes the *product* of the mechanical process.’

29. Sir George Ramsay (1800–1871, philosopher and political economist, the first to distinguish between constant and variable capital), *An Essay on the Distribution of Wealth*, Edinburgh, 1836, p. 184.

30. Ricardo, *On the Principles of Political Economy*, p. 131.

31. Incidental ‘false’ expenses of production: the category into which the political economists from Adam Smith onwards relegated the cost of maintaining necessary but unproductive workers, e.g. soldiers, doctors etc.

32. As in Carey, *Principles of Political Economy*, Pt I, p. 338.

33. Bastiat et Proudhon, *Gratuité du crédit*, pp. 65–74. For Marx’s later discussions of the polemic between Bastiat and Proudhon, see pp. 640–41, 754–8, 843–5.

34. ‘A distinction is to be drawn between this, on one side, and the accumulation of capitals, on the other; the latter presupposes its relations to labour, prices (fixed capital and circulating capital), interest and profit.’ Our reconstruction is based on a comparison with the passage on p. 310 where a distinction is drawn between ‘capital in the process of its becoming’ and ‘the later relations’ or ‘the specific form in which capital is posited at a *certain* point’. Marx is repeating this distinction here, but in a different manner.

35. Ricardo, *On the Principles of Political Economy*, pp. 1–3.

36. See above, pp. 297–303.

37. The expression in full is *‘travailler pour le roi de Prusse’* (‘to work for the king of Prussia’), i.e. to work for the purposes of another without recompense.

38. See below, pp. 883–5.

39. *The Times*, London, Saturday, 21 November 1857, No. 22,844, p. 9. ‘Negroes and the Slave Trade. To the Editor of *The Times.* By Expertus.’ Marx’s English in this sentence has been changed to conform to modern usage.

40. See below, pp. 419–20, 464–9, 471–514, 547–8.

41. This is a generalized reference to Malthus’s numerous discussions of value, e.g. in *Principles of Political Economy*, London, 1836, pp. 50–135, *The Measure of Value*, London, 1823, and *Definitions in Political Economy,* London, 1827, pp. 23–36.

42. Ricardo’s polemic against Smith, in *On the Principles of Political Economy*, pp. 4–12; Ricardo on the effect on value of difficulties of production, pp. 60–67; the essential difference between value and wealth, p. 320; the theory of ground rent, pp. 53–75; the theory of international trade, pp. 131–61.

43. Adam Smith, *Wealth of Nations*, Vol. II, p. 356.

44. Victor, Marquis de Mirabeau (1715–89), was an eccentric French aristocrat converted by Quesnay to the cause of Physiocracy in the 1750s, who subsequently wrote two of the main Physiocratic works, the *Théorie de l’impôt* (1760) and the *Philosophie rurale* (1763).

45. A reference back to the brief discussion of Ricardo on pp. 326–7.

46. Ricardo, *On the Principles of Political Economy*, pp. 120–25.

47. pp. 326–7.

48. Cf. Hegel, *Science of Logic*, pp. 131–7, especially p. 132: ‘Something’s own boundary posited by it as a negative which is at the same time essential, is not merely boundary as such but barrier.’ Also, p. 135: ‘The sentient creature, in the limitation of hunger, thirst, etc., is the drive to go beyond its limiting barrier, and it does overcome it.’

49. Leonard Horner (1785–1864) was originally a geologist, and from 1833 to 1860 Chief Factory Inspector in Lancashire. His many reports on factory conditions there were an important source for Marx in the writing of *Capital*; the reference here would be to one of Horner’s reports on the breaches of the Ten Hours’ Act committed by manufacturers during the 1850s.

50. This is a slip of the pen on Marx’s part. The ‘previous relation’ was 6/8 = 12/16, not 5/8 = 10/16. Therefore the total surplus value was higher by 3/16 not 5/16.

51. This should read 999/1,000,000 = 1/(1,001 + 1/999).

52. In English in the original.

53. This seems to refer back to the value of the capital rather than the material production (the latter would still be 26s.).

54. Babbage, *Traité sur l’économie des machines et des manufactures*, pp. 218–19.

55. The ‘perceptive’ publisher was the editor of Eugène Daire (1798–1847), who issued the works of the Physiocrats during the 1840s. The comments on Boisguillebert are in *Économistes financiers du XVIIIe siècle,* Paris, 1843, p. 419, notes 1 and 2.

56. Ricardo, *On the Principles of Political Economy*, pp. 88–92.

57. Ricardo, *On the Principles of Political Economy*, pp. 327–8.

58. Ricardo, *On the Principles of Political Economy*, pp. 29–35

59. This refers to Marx's notebooks of excerpts from the works of Ricardo, with Marx's critical commentary. A section of one of the excerpt-books in this series is published in *Grundrisse* (MELI), pp. 787–839. Marx wrote these notebooks, which contain, additionally, excerpts from ten works by other authors, as well as from various volumes of *The Economist*, in early 1851. See *Grundrisse* (MELI), p. 782 n.

60. The following sentence appears in the upper margin of this page of the manuscript, without indication of the place in the text where it might be inserted: '(*Money* for itself has to be termed neither use value nor exchange value, but *value*.)'

61. Ricardo, *On the Principles of Political Economy*, pp. 327–8.

62. A reference to Marx's own excerpt-book VIII. Ricardo's doctrine of foreign trade (*On the Principles of Political Economy*, pp. 131–8) is covered in *Grundrisse* (MELI), pp. 808–11.

63. Ricardo, *On the Principles of Political Economy*, pp. 416–17.

64. See above, n. 41.

65. Cf. Hegel, *Science of Logic*, pp. 450–56, e.g. p. 451: 'Matter is that which is indifferent to form.'

66. This should be 32, not 16, since 2/5 of 40 is itself already 16.

67. This should be 40%. In these passages, the use of the term 'interest' (*Zins*) is, strictly speaking, incorrect; it should read 'surplus value'. Similarly, in some passages further on, the terminology does not correspond in every case with Marx's later usage.

NOTEBOOK IV: The Chapter on Capital (continuation)

1. Carey, *Principles of Political Economy*, pp. 15–16, 27–48.

2. Dr Richard Price (1723–91; Nonconformist minister and writer on political and financial subjects), *An Appeal to the Public on the Subject of the National Debt*, London, 1772, p. 19. See below, pp. 842–3.

3. In 1786 William Pitt the Younger established a sinking fund of £1,000,000 in accordance with Dr Price’s proposals.

4. 50: material of labour; 10: instrument of labour; 40: wages of labour.

5. The numerical examples above and below contained occasional, always trivial, errors of arithmetic. The corrections, as indicated by MELI, have been implicitly substituted here, unless noted.

6. In the following table the quantity of value is always expressed in thalers.

7. C. Babbage, *Traité sur l’économie des machines et des manufactures*, p. 29.

8. Bastiat et Proudhon, *Gratuité du crédit,* pp. 127–32, 135–7, 288.

9. Ricardo, *On the Principles of Political Economy,* pp. 117–19.

10. This is a continuation of the critique of Ricardo, broken off on p. 353.

11. See below, pp. 765–71.

12. Lauderdale, *Recherches sur la nature et l’origine de la richesse publique*, p. 137.

13. See above, pp. 373–8.

14. Quotations taken from pp. 4–6 of an anonymous pamphlet published in London in 1821 and entitled *The Source and Remedy of the National Difficulties, deduced from principles of political economy in a letter to*

Lord John Russell.

15. Ravenstone, *Thoughts on the Funding System and its Effects,* pp. 11, 13, 45–6.

16. The original text has ‘more productive’ here.

17. See below, pp. 459–515.

18. Cf. Hegel, *Science of Logic*, pp. 546–7.

19. Cf. Hegel, *Science of Logic* (tr. A. V. Miller), p. 71: ‘That into which the movement returns as into its *ground* is (also) *result.*’

20. See above, p. 401.

21. Marx wrote this sentence in English. The word ‘spurred’ is a suggested emendation in place of the word ‘occurred’ which appears in the original text.

22. J. R. MacCulloch (1789–1864), statistician and economist, editor of the *Scotsman* from 1818 to 1828, Professor of Political Economy in London from 1828 to 1832, ‘past master in pretentious cretinism’, ‘at once the vulgarizer of Ricardian economics and the most pitiful image of its dissolution’ (Marx).

23. MacCulloch, The *Principles of Political Economy,* Edinburgh, 1825, pp. 166–90.

24. James Mill, *Éléments d’économie politique,* Paris, 1823, pp. 250–60.

25. Bastiat et Proudhon, *Gratuité du crédit*, pp. 65–74. For Marx’s later discussions of the polemic between Bastiat and Proudhon, see pp. 640–41, 754–8, 843–5.

26. A reference to the pamphlet *The Currency Question. The Gemini Letters,* London, 1844, written by two upholders of the currency doctrines of the Birmingham banker Thomas Attwood, T. B. Wright and J. Harlow. See below, pp. 804–5.

27. Heinrich Friedrich Storch (1766–1835), Professor of Political Economy in the Russian Academy of Sciences at St Petersburg. Say issued Storch’s work *Cours d’économie politique* with critical notes in 1823; he attacked Say’s interpretation of his views in *Considérations sur la nature du revenu national*, Paris, 1824, pp. 144–59.

28. Malthus, *Principles,* p. 405; *Definitions,* pp. 258–9. Sismondi, *Études,* Vol. I, p. 61 n.

29. *‘Socialistically’:* in the manner of the early utopian socialists, in particular

John Gray; see above, pp. 153–6.

30. Ricardo, *On the Principles of Political Economy,* pp. 80–85.

31. Adam Smith, *Wealth of Nations,* pp. 244–6.

32. Thomas Hodgskin (1787–1869) was a socialist journalist and agitator active in the 1820s. In his economic works he developed the socialist implications in Ricardo's theory of value, in particular in *Labour Defended against the Claims of Capital* (1825) and *Popular Political Economy* (1827).

33. Hodgskin, *Popular Political Economy,* pp. 245–6.

34. *The Source and Remedy of the National Difficulties,* London, 1821, pp. 17–18.

35. *An Inquiry into those Principles Respecting the Nature of Demand and the Necessity of Consumption Lately Advocated by Mr Malthus,* anonymous pamphlet, London, 1821, p. 59.

36. Hodgskin, *Popular Political Economy,* p. 238.

37. ibid., p. 246.

38. Malthus, *Principles of Political Economy,* pp. 266, 301, 302, 315, 372–82, in part paraphrased by Marx.

39. ibid., p. 405, note by the editor, William Otter.

40. ibid., p. 414, note by Malthus.

41. See above, p. 411, and note 24.

42. Say, *Traité d'économie politique,* pp. 142–56.

43. Marx wrote 'not else' in English here.

44. Bastiat et Proudhon, *Gratuité du crédit,* pp. 207–8.

45. For Bastiat’s view, see *Gratuité du* crédit, pp. 127–32.

46. Marx wrote 4 9/20 thalers when he meant to write 4 10/20 thalers. This naturally affects the subsequent calculations, which should be amended as follows: 80 lb. at 4 10/20 thalers a pound = 360 thalers. 360 thalers + 90 = 270. 270 − 216 = 54. 360 − 54 = 306. 54 represents 15% profit on 360 thalers.

47. The substitution of ‘wheat’ for ‘grain’ here and at subsequent points has no bearing on Marx’s argument. He uses the two words interchangeably.

48. Samuel Jones Loyd (1796–1883, banker and economist, expert witness before the Parliamentary Commissions of 1833, 1840, 1848, and 1857, author of numerous pamphlets on money and banking, leading theorist of the Currency School in the controversy over Peel’s Act of 1844, created Baron Overstone in 1860). The source of this quotation has not been found; it is most probably from the *Evidence Presented to the House of Commons Select Committee of 1857,* ed. J. R. MacCulloch, London, 1858.

49. Cf. Hegel, *Science of Logic,* pp. 344–7.

50. This sentence is in English in the original.

51. Ricardo, *On the Principles of Political Economy,* p. 139.

52. Cf. Hegel, *Science of Logic,* p. 600: ‘This universal Notion contains the three moments: universality, particularity, and individuality.’

53. The original text has ‘personifications’, evidently referring back to ‘conditions’.

54. *Sein für andres* is a basic concept of Hegel’s logic, described in the *Science of Logic* (p. 119 of the translation by A. V. Miller, London, 1969) as ‘a negation of the simple relation of being to itself which is supposed to be determinate being’. However, it is paired, not with *Sein für sich*, but with *Sein in sich* (being in itself, described as ‘something returned into itself out of the being for other’). In any case, it is difficult to detect any relation between Marx’s use of *Sein für andres* and Hegel’s use. The situation is different with the concept of *Sein für sich*, since Hegel described being for self in the *Lesser Logic* (p. 179 of the translation by W. Wallace, Oxford, 1892) in the following way: ‘Being for self is a self-subsistent, the One’, and added ‘The readiest instance of being for self is found in the “I”.’ This comes close to Marx’s ‘each individual … as an end in himself’.

55. Having themselves become = having themselves undergone the process of becoming, as indicated on pp. 459–60.

56. On 22 February 1858, Marx wrote to Lassalle that he was planning three works: (1) a critique of the economic categories or the system of bourgeois economy critically presented, (2) a critique and history of political economy and socialism, and (3) a short historical sketch of the development of economic relations or categories (*Marx-Engels Selected Correspondence,* Moscow n.d., p. 125). Marx referred here to the third work, which he never produced in a completed form. Pages 459–514 of the present edition would no doubt have formed part of it.

57. *Do ut facias:* I give that you may do; *facio ut des:* I do that you may give; *do ut des:* I give that you may give. (Roman law.)

58. That is, with the free workers in manufactures (hand crafts).

59. Steuart, *An Inquiry,* Vol. I, p. 40.

60. Marx did not in fact mention this in the Chapter on Money but rather on pp.

272–3, in the Chapter on Capital.

61. Adam Smith, *Wealth of Nations,* Vol. I, pp. 104–5.

62. State property.

63. The word *Stamm* here refers broadly to any extended kinship grouping; e.g. clan, tribe, *gens,* etc.

64. *Geschlechter* may also refer to the sexes, linguistic groups, generations, etc. It is not entirely certain which of these distinctions Marx had foremost in mind here.

65. This is one possible reconstruction of the sentence beginning ‘The commune’, which has a number of grammatical loose ends in the original. Two other possible variants are presented in *Pre-Capitalist Economic Formations,* tr. J. Cohen, London, 1964, p. 73.

66. Craftsmen, workers.

67. Georg Niebuhr, *Römische Geschichte. Erster Theil. Zweyte, völlig umgearbeitete, Ausgabe,* Berlin, 1827, p. 245.

68. The property of the *quirites,* i.e. the Romans.

69. ‘No Roman citizen was permitted to earn a livelihood as a tradesman or artisan’ (Dionysius of Halicarnassus. *Roman Antiquities*, Bk IV, Ch. 25).

70. The passages in pointed brackets, on pp. 477–8, are taken from Niebuhr’s *Römische Geschichte. Erster Theil,* and in this order: (1) p. 148; (2) pp. 435–6; (3) pp. 614–15 and footnotes 1224 and 1225; (4) pp. 317–18; (5) pp. 326–35.

NOTEBOOK V: The Chapter on Capital (continuation)

1. Cicero, *Letters to Atticus,* Vol. V, 21, lines 10–13; Vol. VI, 1, lines 3–7; Vol. VI, 2, lines 7–10.

2. P.-J. Proudhon, *Système des contradictions économiques,* Vol. II, p. 265.

3. Latin plural of *iugerum,* a Roman measure of land.

4. Political animal; literally, city-dweller.

5. The term *Gemeinwesen* also carries the nuances ‘common essence’, ‘common system’ and ‘common being’.

6. Aliens who resided in Athens but were not classed as citizens.

7. According to Roman tradition, Numa Pompilius was the second king of Rome.

8. Citizens of one Greek city-state who were granted full citizenship in another.

9. Antoine Cherbuliez (1797–1869, Swiss lawyer and economist, follower of Sismondi, although he added some elements of Ricardian theory), *Richesse ou pauvreté: Exposition des causes et des effets de la distribution actuelle des richesses sociales*, Paris, 1841, p. 16.

10. Bastiat et Proudhon, *Gratuité du crédit*, pp. 65–74. For Marx's later discussions of the polemic between Bastiat and Proudhon, see pp. 640–41, 754–8, 843–5.

11. Adam Smith, *Wealth of Nations,* Vol. III, Bk III, Ch. 4.

12. 'This' refers back to 'manufacture'. See the definition of 'factory' given by Ure, cited by Marx on p. 690.

13. This statement is taken directly from Du Cange, *Glossarium mediae et infimae Latinitatis,* ed. G. A. L. Henschel, Paris, 1842, Vol. 2, p. 139, article entitled '2. Capitale'. However, Du Cange was wrong. The word ἀρχεῖα means 'government buildings', never 'loan' or 'principal sum of money owed' as suggested there; the Greek word for loan, which Du Cange probably had in mind, is χρέος.

14. *métairie:* share-cropping, the modern *métayage. Bail de bestes à cheptel:* lease with livestock as capital. Cf. Du Cange, *Glossarium,* Vol. 2, p. 139.

15. 'Those who have to pay a head tax'.

16. Adam H. Müller (1774–1829, leading advocate of the Romantic reaction in history and economics during the early nineteenth century; Austrian state official under Metternich, ennobled for his propagandistic activities), *Die Elemente der Staatskunst, Erster Theil,* Berlin, 1809, pp. 226–41.

17. ‘I shall grant a tenth part of my own to God both in livestock and in dead fruits of the earth’, quoted by Du Cange, *Glossarium*, p. 140, from Athelstan’s Ordinance of 925 on tithes.

18. See above, pp. 457–8.

19. ‘(false!)’ was inserted afterwards, above the line. [MELI note]

20. In English in the original.

21. Marx’s distinction between *Rohstoff* and *Rohmaterial* has no English equivalent. *Rohstoff* is the raw material in its pristine state, before being subjected to human labour; *Rohmaterial* is the raw material which has been formed by human labour but has yet to enter into the final product. Cf. *Capital,* Vol. I, Moscow, 1954, pp. 178–82.

22. See above, p. 402.

23. See above, pp. 256–7.

24. *par excellence.*

25. Cf. Hegel, *System of Philosophy,* I, *Logic,* para. 161: ‘The concept remains at home with itself in its process; no new content is posited by the process, only an alteration of form is produced.’

26. Sismondi, *Nouveaux Principes d’économie politique,* Vol. I, p. 89. See above, p. 261.

27. ibid., Vol. I, pp. 91–2.

28. Cherbuliez, *Richesse ou pauvreté,* p. 64.

29. In Cherbuliez; raw material, instrument of labour, and supply of articles of consumption. See above, p. 299.

30. Cherbuliez, *Richesse ou pauvreté,* pp. 25–6.

31. William Thompson (1783–1833) was an Irish landowner who embraced Owenism, and criticized political economy from a utopian socialist position, but on the basis of Ricardo’s doctrines.

32. ‘That’, i.e. ‘that situation’.

33. ‘Of the same’ (*desselben*) probably refers back to ‘recognition of nature ([and] practical power over nature)’. The contraction is ambiguous.

34. Storch, *Cours d’économie politique,* Vol. I, pp. 411–12.

35. Malthus, *The Measure of Value Stated and Illustrated, with an Application of it to the Alterations in the Value of the English Currency since 1790,* London, 1823, p. 17.

36. William Thompson, *An Inquiry into the Principles of the Distribution of Wealth, Most Conducive to Human Happiness, Applied to the Newly Proposed System of Voluntary Equality of Wealth,* London, 1824, p. 176.

37. Ramsay, *An Essay on the Distribution of Wealth,* p. 55.

38. Incidental ‘false’ expenses of production: the category into which the political economists from Adam Smith onwards relegated the cost of maintaining necessary but unproductive workers, e.g. soldiers, doctors etc.

39. Thomas de Quincey (1785–1859), the essayist, author of *Confessions of an Opium Eater,* was also a writer on political economy, and a follower of Ricardo.

40. Ramsay, *An Essay on the Distribution of Wealth,* p. 43. The references are to the page numbers of Ramsay’s book. The quotations themselves are as usual in a mixture of English and German.

41. ibid., p. 55.

42. Misunderstandings on *Ramsay's* part (cf. Ramsay, *An Essay,* p. 22 n.) in which he followed Ricardo's own misunderstandings (cf. Ricardo, *On the Principles of Political Economy,* pp. 5, 7–8, 9).

43. Adam Smith, *Wealth of Nations,* Vol. I, pp. 101–2, 131–4.

44. Ricardo, *On the Principles of Political Economy,* pp. 338–9.

45. ibid., p. 3: 'In speaking of commodities … we mean commodities … on the production of which competition operates without restraint.'

46. ibid., p. 86.

47. De Quincey, *The Logic of Political Economy,* Edinburgh, 1844, p. 204.

48. De Quincey, *Logic of Political Economy,* p. 204.

NOTEBOOK VI: The Chapter on Capital (continuation)

1. Carey, *Principles of Political Economy,* Part I, p. 99.

2. J. R. MacCulloch, *The Principles of Political Economy,* London, 1825, pp. 313–18.

3. The extracts from Ricardo appear in a 'Notebook VIII' of an earlier series of notebooks dated 1851. Excerpts are printed in *Grundrisse* (MELI) as an appendix, omitted in the present edition.

4. R.5: Ricardo, *On the Principles of Political Economy,* p. 5 (in fact p. 3).

5. The page numbers in Ricardo refer to the third edition (1821).

6. Bray, *Labour's Wrongs,* p. 48.

7. Adam Smith, *Wealth of Nations,* Vol. I, pp. 100–102, 130–31.

8. Marx, here as elsewhere, quotes in his own abbreviated German. The text therefore differs slightly from Ricardo's original. Compare Ricardo, *Principles,* p. 5.

9. Wakefield, *A View of the Art of Colonization,* p. 169.

10. Should read 4.7%, but the error has been taken over from Malthus himself. Cf. Malthus, *Principles of Political Economy,* pp. 269–70. Two other petty errors of arithmetic in these passages have been corrected as indicated by the MELI editors.

11. Ravenstone, *Thoughts on the Funding System,* p. 11.

12. Malthus, *The Measure of Value,* p. 33.

13. ibid.

14. Malthus, The *Measure of Value,* p. 29.

15. Carey, *Principles of Political Economy,* Part I, pp. 76–8.

16. ibid., p. 99.

17. Adam Smith, *Wealth of Nations,* Vol. I, pp. 230–31, note by Wakefield the editor.

18. Albert Gallatin (1761–1849; American public figure of Swiss origin, academic, diplomat, and banker, author of many books on financial questions), *Considerations on the Currency and Banking System of the United States,* Philadelphia, 1831, p. 68.

19. John Wade (1788–1875) was a journalist and historian, and parliamentary reformer, who worked for a long time with the *Spectator,* and whose *History of the Middle and Working Classes* was described by Marx as ‘theoretically … original in some parts … historically … a shameless plagiarism from Sir F. M. Eden’.

20. Gaskell, *Artisans and Machinery,* pp. 111–14.

21. Babbage, *Traité sur l’économie,* p. 485.

22. Pellegrino Rossi (1787–1848; Italian political economist, supporter of

Napoleon I, in exile from 1815, first in Geneva then in France, professor of political economy at the Collège de France 1833–40, created a peer in 1844, returned to Italy as French ambassador, became prime minister of the Pope's government in 1848, finally assassinated in the course of a speech in favour of moderation), *Cours d'économie politique,* Brussels, 1843.

23. R. Torrens, *An Essay on the Production of Wealth,* London, 1821, pp. 70–71.

24. Labour in being, not in potency.

25. Cf. Ricardo, *On the Principles of Political Economy,* pp. 31–2, 'There can be no rise in the value of labour without a fall of profits … If cloth … be divided between the workman and his employer, the larger the proportion given to the former, the less remains for the latter.'

26. H. C. Carey, *The Past, the Present, and the Future,* Philadelphia, 1848, pp. 74–5.

27. The Reverend Thomas Chalmers (1780–1847) was a Scottish Presbyterian minister who taught moral philosophy and divinity, as well as political economy; 'one of the most fanatical Malthusians' (Marx).

28. F.-L.-A. Ferrier, *Du gouvernement considéré dans ses rapports avec le commerce,* Paris, 1805, p. 35. Ferrier (1777–1861) was a high French customs official who both operated and wrote in favour of Napoleon I's protective system.

32. Ricardo, *On the Principles of Political Economy,* p. 493.

33. *Recherches sur la nature et les causes de la richesse des nations;* traduction nouvelle, avec des notes et observations; par Germain Garnier, Paris, 1802, 2 volumes. The French edition of Adam Smith, excerpted by Marx already in 1844; see *MEGA.* 1/3, pp. 457–93.

34. Genesis iii, 19.

35. *grisette:* young shop-girl.

36. Fourier, *Le Nouveau Monde industriel et sociétaire,* in *OEuvres complets,* Paris, 1848, Vol. VI, pp. 245–52.

37. Nassau Senior, *Principes fondamentaux,* pp. 309–35.

38. Bastiat et Proudhon, *Gratuité du crédit,* p. 200.

39. Malthus, *Definitions in Political Economy,* pp. 69–70.

40. Adam Smith, *Wealth of Nations,* Vol. II, Bk II, Ch. 2, pp. 270–77.

41. ‘Subjects of exchange’ should clearly read ‘objects of exchange’. [MELI note]

42. See above, p. 617.

43. See above, p. 585.

44. Bastiat and Proudhon, *Gratuité du crédit*, p. 200.

45. ibid., p. 288.

46. A. Anderson (Scottish chemical manufacturer, not to be confused with James Anderson, Scottish farmer, and eighteenth-century originator of the theory of ground rent), *The Recent Commercial Distress; or, the Panic, Analysed: Showing the Cause and Cure,* London, 1847.

47. Say, *Traité d'économie politique*, Vol. II, p. 430.

48. Ramsay, *An Essay on the Distribution of Wealth.*

49. Ricardo, *On the Principles of Political Economy*, pp. 26–7. The passage is sometimes compressed, sometimes expanded, in the quoting, in line with Marx's usual method in the notebooks.

50. Petty, *Political Arithmetic,* pp. 178–9.

51. 'Assert' is a suggested emendation for 'overlook' as found in the original text.

52. Sismondi, *Nouveaux Principes d'économie politique*, Vol. I, pp. 94–8.

53. Cherbuliez, *Richesse ou pauvreté*, pp. 16–19.

54. The number 29 refers to Notebook V, p. 29. See above, p. 543, and Storch, *Cours d'économie politique,* Vol. I, pp. 411–12.

55. Storch, *Cours d'économie politique*, Vol. I, p. 246. The number 26a refers to an excerpt-book.

56. Storch, *Considérations sur la nature du revenu national*, Paris, 1824.

57. Ricardo, *On the Principles of Political Economy,* p. 3.

58. ‘Middle-class’: in English in the original text.

59. A reference to the pamphlet *The Currency Question. The Gemini Letters,* London, 1844, written by two upholders of the currency doctrines of the Birmingham banker Thomas Attwood, T. B. Wright and J. Harlow. See below, pp. 804–5.

60. Ramsay, *An Essay on the Distribution of Wealth,* p. 43.

61. The quotation from Storch is on p. 637.

62. By de Quincey and Ramsay; see above, pp. 642–3.

63. See above, p. 592, and Rossi, *Cours d’économie politique,* p. 370.

64. Storch, *Cours d’économie politique,* Vol. I, p. 405.

65. Malthus, *Definitions in Political Economy,* pp. 237–8.

66. Adam Smith, *Recherches sur la nature et les causes de la richesse des nations,* Vol. II, pp. 197–8.

67. *‘partir de son possesseur’.* Storch, *Cours d’économie politique,* Vol. I, p. 405.

68. ‘Use value’: this ought to read ‘exchange value’.

69. Cherbuliez, *Richesse au pauvreté,* pp. 14–15.

70. Malthus, *Definitions in Political Economy,* pp. 237–8.

71. See above, p. 574, and Malthus, *The Measure of Value,* p. 33.

72. See above, pp. 644–5.

73. MacCulloch, *The Principles of Political Economy,* p. 300.

74. Ricardo, *On the Principles of Political Economy,* p. 26.

75. J.-B. Say, *Traité d’économie politique,* Vol. II, p. 430.

76. Sismondi, *Nouveaux Principes d’économie politique,* Vol. I, pp. 94–8.

77. *The Economist,* Vol. V, No. 219, 6 November 1847, p. 1271.

78. Ravenstone, *Thoughts on the Funding System,* p. 45.

79. Babbage, *Traité sur l’économie des machines et des manufactures,* pp. 20–21.

80. Andrew Ure (1778–1857; Scottish doctor, chemist, astronomer, apologist for the factory system of the early nineteenth century and opponent of the Factory Acts), *Philosophie des manufactures,* Brussels, 1836 (French translation of the 2nd edition, London, 1835), Vol. I, pp. 18–19.

NOTEBOOK VII: The Chapter on Capital (continuation)

1. The manuscript has: '… now appears as circulating capital (the first two) and fixed capital'.

2. Hodgskin, *Labour Defended,* p. 16.

3. *'als hätt es Lieb im Leibe',* Goethe, *Faust,* Pt I, Act 5, Auerbach's Cellar in Leipzig.

4. See p. 688, n. 77.

5. Fourier, *Le Nouveau Monde industriel et sociétaire,* Vol. VI, pp. 242–52.

6. The author referred to here may be J. F. Hodges, who wrote *Lessons on Agricultural Chemistry* (1849), and *First Steps to Practical Chemistry for Agricultural Students* (1857); or Marx may have intended to write 'Hodgskin'.

7. De Quincey, *The Logic of Political Economy,* p. 114.

8. Babbage, *Traité sur l'économie des machines et des manufactures,* pp. 375–6.

9. See below pp. 843–5.

10. *The Economist,* Vol. V, No. 219, 6 November 1847, p.1271.

11. *The Economist,* Vol. V, No. 219, 6 November 1847, p. 1271.

12. ibid

13. The first part of this quotation is taken over by Storch from the French edition of Adam Smith, Vol. II, p. 207 (see above, p. 728); the whole quotation, with the addition of Storch's remark about revenue, is to be found in Storch, *Cours d'économie politique,* Vol. I, p. 246.

14. Cf. Hegel, *Science of Logic*, p. 746: 'The relation of the activity of the end through the means to the external object is … an immediate relation of the

middle term to the other extreme. It is immediate because the middle term has an external object in it and the other extreme is another such object.'

15. Sir Frederick Morton Eden, Bt (1766–1809) was inspired by the high prices of 1794 and 1795 to make the first ever investigation into working-class history. 'The only disciple of Adam Smith throughout the eighteenth century who produced anything of importance' (Marx).

16. The passages from Eden's book (Vol. I, Bk 1) are as follows, beginning with the passage on p. 735 of the present edition: pp. 1–2; pp. 57–61; pp. 75–6; p. 100; p. 101.

17. Adam Smith, *Recherches sur la nature et les causes de la richesse des nations,* Vol. II, p. 226.

18. Adam Smith, *Recherches sur la nature et les causes de la richesse des nations,* Vol. II, pp. 197–8.

19. Say, *Traité d'économie politique,* Vol. II, p. 185.

20. See above, pp. 333–53.

21. The sentence preceding this one was inserted by Marx, above the line, in English; thus the apparent virtual repetition. (The sentence following also appears in English in the original.)

22. Adam Smith, *Recherches sur la nature et les causes de la richesse des nations,* Vol. I, p. 193.

23. Ricardo, *On the Principles of Political Economy,* pp. 338–9.

24. Ramsay, *An Essay,* pp. 179–80.

25. Marx made extracts from these works on organic chemistry: J. von Liebig, *Die organische Chemie,* 4th edn, Brunswick, 1842; J. F. W. Johnston, *Lectures on Agricultural Chemistry and Geology,* 2nd edn, London, 1847; and J. F. W. Johnston, *Catechism of Agricultural Chemistry and Geology,* Edinburgh, 1849.

26. See the section on Bastiat and Carey, pp. 883–93.

27. In fact, see below pp. 889–90.

28. See p. 86, n. 7.

29. Sismondi, *Nouveaux Principes,* Vol. I, p. 90.

30. op. cit., Vol. I, p. 82.

31. op. cit., Vol. I, p. 89.

32. Torrens, *An Essay on the Production of Wealth,* p. 52.

33. $s/(c + v) < s/v$ is the correct expression; but the manuscript has: $(c + v)/s < v/s$, struck out but not replaced by anything else. [MELI note]

34. Robert Owen, *Six Lectures Delivered in Manchester,* Manchester, 1837, p. 58; see above, pp. 712–14.

35. Benjamin Thompson (1753–1814), American adventurer, who entered the service of George III, was created Count of Rumford in 1784, issued *Essays, Political, Economical, and Philosophical,* in London, 1796–1802, in which he recommended various inferior forms of food for labourers; discussed by Marx in *Capital,* Vol I, Moscow 1954, p. 601.

36. The MELI edition gives *aufgelöst* (dissolved) rather than *ausgelöst* (triggered, released). This is in all probability a misreading of the handwritten manuscript. (The *f* and one form of the *s* are virtually indistinguishable in the old-style German script Marx used at that time.)

37. Wakefield’s note on p. 64 of Vol. I of his edition of Adam Smith (London, 1835–9).

38. Steuart, *An Inquiry into the Principles of Political Economy,* Vol. I, p. 399.

39. ibid., pp. 403–5.

40. Geminiano Montanari, *Della moneta, trattato mercantile,* in Custodi (ed.), Scrittori Classici Italiani di Economia Politica, Parte Antica, Tomo III, Milan, 1804.

41. Tuckett, *A History,* Vol. I, p. 157 n.

42. ibid., p. 204.

43. Eden, *The State of the Poor,* Vol. I., pp. 119–20.

44. Marx collected and annotated an immense amount of material on the various theories of the exchange rate: he included this in a draft of 1854–5 entitled ‘Money System, Credit System, and Crises’. This manuscript remains unpublished.

45. *The Economist,* Vol. XVI, No. 759, 13 March 1858, p. 290, article entitled ‘Will the Low Rate of Interest Last?’.

46. David Urquhart, *Familiar Words as Affecting England and the English* London, 1856, p. 112.

47. See above, p. 782, quotation from Steuart.

48. ‘Sterlings’ in the original text.

49. Marx’s English in the above sentence has been altered to conform to modern usage. His use, in these and other passages, of terms which today have an offensive ring (e.g. ‘semi-civilized’, ‘uncivilized’, ‘savage’, ‘semi-savage’, where what is meant is simply ‘pre-capitalist’) reflects the general blindness of European scholarship towards non-European civilizations, and indicates the relative weakness of anti-colonial political movements at the time. This did not prevent Marx from being an enemy of colonialism and of great-power chauvinism in every form.

50. The wars of the Revolutionary and Napoleonic periods, 1793–1815.

51. Cobbett, *Paper against Gold,* London, 1828, p. 2.

52. Literally, ‘toads’. A French term of abuse.

53. Garnier, *Histoire de la monnaie,* Vol. II, p. 11.

54. ‘King Servius first stamped money with the image of sheep and oxen.’

55. ‘Unwrought gold, unwrought silver’.

56. *The Economist,* Vol. I, No. 37, 11 May 1844, p. 771, article entitled ‘The First Step in the Currency Question – Sir Robert Peel’.

57. *The Economist,* Vol. I, No. 42, 15 June 1844, p. 890, article entitled ‘The Action of Money on Prices’.

Book I: The Process of Production of Capital

Part One: Commodities and Money

Chapter 1: The Commodity

1. The Two Factors of the Commodity: Use-Value and Value (Substance of Value, Magnitude of Value) 125
2. The Dual Character of the Labour Embodied in Commodities 131
3. The Value-Form, or Exchange-Value 138
   (a) The Simple, Isolated, or Accidental Form of Value 139
      (1) The two poles of the expression of value: the relative form of value and the equivalent form 139
      (2) The relative form of value 140
         (i) The content of the relative form of value 140
         (ii) The quantitative determinacy of the relative form of value 144
         (iii) The equivalent form 147
         (iv) The simple form of value considered as a whole 152
   (b) The Total or Expanded Form of Value 154
      (1) The expanded relative form of value 155
      (2) The particular equivalent form 156
      (3) Defects of the total or expanded form of value 156

- (c) The General Form of Value 157
  - (1) The changed character of the form of value 157
  - (2) The development of the relative and equivalent forms of value: their interdependence 160
  - (3) The transition from the general form of value to the money form 162
- (d) The Money Form 162

4. The Fetishism of the Commodity and Its Secret 163

Chapter 2: The Process of Exchange 178

Chapter 3: Money, or the Circulation of Commodities 188

1. The Measure of Values 188
2. The Means of Circulation 198
   - (a) The Metamorphosis of Commodities 198
   - (b) The Circulation of Money 210
   - (c) Coin. The Symbol of Value 221
3. Money 227
   - (a) Hoarding 227
   - (b) Means of Payment 232
   - (c) World Money 240

Part Two: The Transformation of Money into Capital

Chapter 4: The General Formula for Capital 247

Chapter 5: Contradictions in the General Formula 258

Chapter 6: The Sale and Purchase of Labour-Power 270

Part Three: The Production of Absolute Surplus-Value

Chapter 7: The Labour Process and the Valorization Process 283

1. The Labour Process 283
2. The Valorization Process 293

Chapter 8: Constant Capital and Variable Capital 307

Chapter 9: The Rate of Surplus-Value 320

1. The Degree of Exploitation of Labour-Power 320
2. The Representation of the Value of the Product by Corresponding Proportional Parts of the Product 329
3. Senior's 'Last Hour' 333
4. The Surplus Product 338

Chapter 10: The Working Day 340

1. The Limits of the Working Day 340
2. The Voracious Appetite for Surplus Labour. Manufacturer and Boyar 344
3. Branches of English Industry without Legal Limits to Exploitation 353
4. Day Work and Night Work. The Shift System 367

5. The Struggle for a Normal Working Day. Laws for the Compulsory Extension of the Working Day, from the Middle of the Fourteenth to the End of the Seventeenth Century 375
6. The Struggle for a Normal Working Day. Laws for the Compulsory Limitation of Working Hours. The English Factory Legislation of 1833–64 389
7. The Struggle for a Normal Working Day. Impact of the English Factory Legislation on Other Countries 411

Chapter 11: The Rate and Mass of Surplus-Value 417

Part Four: The Production of Relative Surplus-Value

Chapter 12: The Concept of Relative Surplus-Value 429

Chapter 13: Co-operation 439

Chapter 14: The Division of Labour and Manufacture 455
1. The Dual Origin of Manufacture 455
2. The Specialized Worker and His Tools 458
3. The Two Fundamental Forms of Manufacture – Heterogeneous and Organic 461
4. The Division of Labour in Manufacture, and the Division of Labour in Society 470
5. The Capitalist Character of Manufacture 480

Chapter 15: Machinery and Large-Scale Industry 492
1. The Development of Machinery 492
2. The Value Transferred by the Machinery to the Product 508
3. The Most Immediate Effects of Machine Production on the Worker 517
   (a) Appropriation of Supplementary Labour-Power by Capital. The Employment of Women and Children 517
   (b) The Prolongation of the Working Day 526
   (c) Intensification of Labour 533
4. The Factory 544
5. The Struggle between Worker and Machine 553
6. The Compensation Theory, with Regard to the Workers Displaced by Machinery 565
7. Repulsion and Attraction of Workers through the Development of Machine Production. Crises in the Cotton Industry 575
8. The Revolutionary Impact of Large-Scale Industry on Manufacture, Handicrafts and Domestic Industry 588
   (a) Overthrow of Co-operation Based on Handicrafts and on the Division of Labour 588
   (b) The Impact of the Factory System on Manufacture and Domestic Industries 590

    - (c) Modern Manufacture 592
    - (d) Modern Domestic Industry 595
    - (e) Transition from Modern Manufacture and Domestic Industry to Large-Scale Industry. The Hastening of this Revolution by the Application of the Factory Acts to those Industries 599
  9. The Health and Education Clauses of the Factory Acts. The General Extension of Factory Legislation in England 610
  10. Large-Scale Industry and Agriculture 636

Part Five: The Production of Absolute and Relative Surplus-Value

Chapter 16: Absolute and Relative Surplus-Value 643

Chapter 17: Changes of Magnitude in the Price of Labour-Power and in Surplus-Value 655
  1. The Length of the Working Day and the Intensity of Labour Constant; the Productivity of Labour Variable 656
  2. The Length of the Working Day and the Productivity of Labour Constant; the Intensity of Labour Variable 660
  3. The Productivity and Intensity of Labour Constant; the Length of the Working Day Variable 662
  4. Simultaneous Variations in the Duration, Productivity and Intensity of Labour 664

Chapter 18: Different Formulae for the Rate of Surplus-Value 668

Part Six: Wages

Chapter 19: The Transformation of the Value (and Respectively the Price) of Labour-Power into Wages 675

Chapter 20: Time-Wages 683

Chapter 21: Piece-Wages 692

Chapter 22: National Differences in Wages 701

Part Seven: The Process of Accumulation of Capital

Chapter 23: Simple Reproduction 711

Chapter 24: The Transformation of Surplus-Value into Capital 725
  1. Capitalist Production on a Progressively Increasing Scale. The Inversion which Converts the Property Laws of Commodity Production into Laws of Capitalist Appropriation 725
  2. The Political Economists' Erroneous Conception of Reproduction on an Increasing Scale 734

3. Division of Surplus-Value into Capital and Revenue. The Abstinence Theory 738
4. The Circumstances which, Independently of the Proportional Division of Surplus-Value into Capital and Revenue, Determine the Extent of Accumulation, namely, the Degree of Exploitation of Labour-Power, the Productivity of Labour, the Growing Difference in Amount between Capital Employed and Capital Consumed, and the Magnitude of the Capital Advanced 747
5. The So-Called Labour Fund 758

Chapter 25: The General Law of Capitalist Accumulation 762

1. A Growing Demand for Labour-Power Accompanies Accumulation if the Composition of Capital Remains the Same 762
2. A Relative Diminution of the Variable Part of Capital Occurs in the Course of the Further Progress of Accumulation and of the Concentration Accompanying it 772
3. The Progressive Production of a Relative Surplus Population or Industrial Reserve Army 781
4. Different Forms of Existence of the Relative Surplus Population. The General Law of Capitalist Accumulation 794
5. Illustrations of the General Law of Capitalist Accumulation 802
   - (a) England from 1846 to 1866 802
   - (b) The Badly Paid Strata of the British Industrial Working Class 808
   - (c) The Nomadic Population 818
   - (d) Effect of Crises on the Best Paid Section of the Working Class 822
   - (e) The British Agricultural Proletariat 828
   - (f) Ireland 854

Part Eight: So-Called Primitive Accumulation

Chapter 26: The Secret of Primitive Accumulation 873

Chapter 27: The Expropriation of the Agricultural Population from the Land 877

Chapter 28: Bloody Legislation against the Expropriated since the End of the Fifteenth Century. The Forcing Down of Wages by Act of Parliament 896

Chapter 29: The Genesis of the Capitalist Farmer 905

Chapter 30: Impact of the Agricultural Revolution on Industry. The Creation of a Home Market for Industrial Capital 908

Chapter 31: The Genesis of the Industrial Capitalist 914

Chapter 32: The Historical Tendency of Capitalist Accumulation 927

Chapter 33: The Modern Theory of Colonization 931

Appendix: Results of the Immediate Process of Production
  Introduction by Ernest Mandel 943
  I. Commodities as the Product of Capital 949
  II. Capitalist Production as the Production of Surplus-Value 975
  III. Capitalist Production is the Production and Reproduction of the Specifically Capitalist Relations of Production 1060
  IV. Isolated Fragments 1066
Quotations in Languages Other than English and German 1085
Index of Authorities Quoted 1095
General Index 1121
Note on Previous Editions of the Works of Marx and Engels 1137
Chronology of Works by Marx and Engels 1138

Introduction

When Volume 1 of *Capital* was first published, capitalist industry, though predominant in a few Western European countries, still appeared as an isolated island encircled by a sea of independent farmers and handicraftsmen which covered the whole world, including the greater part even of Europe. What Marx's *Capital* explained, however, was above all the ruthless and irresistible impulse to growth which characterizes production for private profit and the predominant use of profit for capital accumulation. Since Marx wrote, capitalist technology and industry have indeed spread all over the world. As they have done so, moreover, not only have material wealth and the possibilities for freeing mankind definitively from the burden of meaningless, repetitive and mechanical work increased, but so too has the polarization of society between fewer and fewer owners of capital and more and more workers of hand and brain, forced to sell their labour-power to these owners. The concentration of wealth and power in a small number of giant industrial and financial corporations has brought with it an increasingly universal struggle between Capital and Labour.

Periodically the bourgeois class and its ideologues have thought they have found the stone of wisdom; have felt able, accordingly, to announce the end of crises and socio-economic contradictions in the capitalist system. But despite Keynesian techniques, notwithstanding all the various attempts to integrate the working class into late capitalism, for over a decade now the system has appeared if anything more crisis-ridden than when Marx wrote *Capital*. From the Vietnam war to the turmoil of the world monetary system; from the upsurge of radical workers' struggles in Western Europe since 1968 to the rejection of bourgeois values and culture by large numbers of young people throughout the world; from the ecology and energy crises to the recurrent economic recessions: there is no need to look very far for indications that capitalism's heyday is over. *Capital* explains why the sharpening contradictions of the system were as inevitable as its impetuous growth. In that sense, contrary to a generally accepted belief, Marx is much more an economist of the twentieth century than of the nineteenth. Today's Western world is much nearer to the 'pure' model of *Capital* than was the world in which it was composed.

I. THE PURPOSE OF *CAPITAL*

In *Capital* Marx's fundamental aim was to lay bare the laws of motion which govern the origins, the rise, the development, the decline and the disappearance of a given social form of economic organization: the capitalist mode of production. He was not seeking *universal* laws of economic organization. Indeed, one of the essential theses of *Capital* is that no such laws exist. For Marx, there are no economic laws valid for each and every basically different form of society (aside from trivialities like the formula which points out that no society can consume more than it produces without reducing its stock of wealth – whether the natural fertility of the land, the total population, the mass of means of production, or several of these). Each specific social form of economic organization has its own specific economic laws. *Capital* limits itself to examining those which govern the capitalist mode of production.

Capital is therefore not 'pure' economic theory at all. For Marx, 'pure' economic theory, that is economic theory which abstracts from a specific social structure, is impossible. It would be similar to 'pure' anatomy, abstracted from the specific species which is to be examined. We can push the analogy further. Although, of course, *comparative anatomy* is a branch of natural science, useful for increasing our knowledge of human and animal physiology, it can be only a by-product of the development of the anatomical understanding of specific given species. In the same way, Marx's theory of historical materialism does indeed include comparative economic analysis – for example an examination of the evolution of human labour, human labour productivity, social surplus product and economic growth, from slave society through feudalism to capitalism. But such comparison can result only from the analysis of specific modes of production, each with its own economic logic and its own laws of motion. These cannot be superseded by or subsumed under 'eternal' economic laws. We can even push the analogy to its final conclusion. If one tries to find some basic common kernel in 'all' anatomy, one leaves the realm of that specific science and enters another: biology or biochemistry. In the same way, if one tries to discover basic working hypotheses valid for 'all' economic systems, one passes from the realm of economic theory to that of the science of social structures: historical materialism.

In this way, Marx's economic theory and its crowning work *Capital* are based upon an understanding of the *relativity, social determination and historical limitation* of all economic laws. In the socio-economic development of mankind, commodity production, market economy or the distribution of social resources among different branches of production by 'objective economic laws' operating 'behind the back of the producers' do not correspond to 'human nature', have not always existed and will not always exist. *Capital*, explaining the origins of the capitalist mode of production, points towards the inevitable historical decline and fall of this same social system. An economic theory based upon the historical relativity of every economic system, its strict limitation in time, tactlessly reminds Messrs the capitalists, their hangers-on and their apologists that capitalism itself is a product of history. It will perish in due course as it once was born. A new social form of economic organization will then take the place of the capitalist one: it will function according to other laws than those which govern the capitalist economy.

Nevertheless, *Capital* does not deal exclusively with the capitalist mode of production, although the discovery of the laws which govern this mode of production is its fundamental objective. Capitalist production is generalized commodity production. Generalized commodity production fully unfolds trends and contradictions which are latent in every one of its basic 'cells', the commodities. It is no accident that Marx starts *Capital* Volume 1 with an analysis neither of 'the capitalist mode of production', nor of capital, nor of wage-labour, nor even of the relations between wage-labour and capital. For it is impossible to analyse any of these basic concepts or categories – which correspond to the basic structure of capitalist society – scientifically, totally and adequately without a previous analysis of value, exchange-value and surplus-value. But these latter categories in turn hinge upon an analysis of the commodity and of commodity-producing labour.

Just as surplus-value and capital emerge *logically* from an analysis of value and exchange-value, so too does the capitalist mode of production emerge *historically* from the growth of commodity production: without simple commodity production no capitalism can come into existence. *Capital*, the *Grundrisse* and the other basic economic writings of Karl Marx therefore include many analyses of simple commodity production, a form of production which existed in manifold ways for nearly 10,000 years before modern capitalism was born, but which found its fullest flowering only between the thirteenth and sixteenth centuries A.D. in the Low Countries, northern Italy, and later Britain (and to a lesser degree in Japan before the Meiji revolution).

Objections have been advanced – by early Russian Marxist authors like Bogdanov, by later commentators like Rubin and by contemporary Marxists like Lucio Colletti and Louis Althusser[1] – to the view, originating with Engels and held by Rosa Luxemburg, to which I subscribe,[2] that Marx's *Capital* provides not only a basic analysis of the capitalist mode of production, but also significant comments upon the whole historical period which includes essential phenomena of petty commodity production. These objections, however, are based upon a double confusion. It is true that the capitalist mode of production is the only social organization of the economy which implies *generalized* commodity production. It would thus be completely mistaken to consider, for example, Hellenistic slave society or the classical Islamic Empire – two forms of society with strongly developed petty commodity production, money economy and international trade – as being *ruled* by the 'law of value'. Commodity production in these precapitalist modes of production is intertwined with, and in the last analysis subordinated to, organizations of production (in the first place agricultural production) of a clearly non-capitalist nature, which follow a different economic logic from that which governs exchanges between commodities or the accumulation of capital.

---

[1] I. I. Rubin, *Essays on Marx's Theory of Value*, Detroit, 1972, pp. 254–6; Lucio Colletti, *Marxism and Hegel*, NLB, London, 1973, pp. 131–2; Louis Althusser, 'The Object of *Capital*', in *Reading Capital*, NLB, London, 1970, pp. 113–17, 124–6. There is also a very illuminating remark by Marx himself, from 'Chapter 6' of *Capital*, Vol. 1 (see Appendix to this volume): 'Nevertheless, within certain limits both goods and money were circulated and hence there was a certain evolution of trade: this was the *premiss* and *point of departure for the formation of capital* and the capitalist mode of production' (pp. 1059–60 below).

[2] Karl Marx, *Capital*, Moscow, 1962, Vol. 3, pp. 172–4; Friedrich Engels, 'Law of Value and Rate of Profit', ibid. (appendix), pp. 873–6; Rosa Luxemburg, *Einführung in die Nationalökonomie*, Berlin, 1925, pp. 199–232; Ernest Mandel, *Marxist Economic Theory*, London, 1969, Vol. 1, pp. 65–8.

But this in no way implies that in societies in which petty commodity production has already become the *predominant* mode of production (that is where the majority of the producers are free peasants and free handicraftsmen who own and exchange the products of their labour), the laws governing the exchange of commodities and the circulation of money do not strongly influence the economic dynamic. Indeed, it is precisely the *unfolding* of the law of value which leads in such societies to the separation of the direct producers from their means of production, although a whole series of social and political developments influences this birth-process of modern capitalism, hastening it, slowing it down, or combining it with trends going in different directions.

On the other hand, if it is true that fully-fledged 'economic accounting based upon quantities of socially equalized labour' comes into its own only under capitalism, and this only as an objective economic law and not as conscious decisions of owners of commodities, it does not follow at all from this statement that 'labour quantities accounting' cannot *begin* to appear in pre-capitalist societies, in which commodity production becomes a regular institution. Indeed, it is precisely when petty commodity production is already largely developed, but at the same time still intertwined with traditional forms of 'natural' economic organization, which imply conscious allocations of economic resources and social labour between different forms of production (through customs, habits, rites, religion, deliberation of elders, assemblies of participants etc.), that the need for a conscious accounting of 'labour quantities' can and must appear, in order to avoid basic injustices and inequalities in social organizations still based upon a high degree of social equality and coherence. I have tried to prove by empirical data that this has in fact been the case, at different historical periods, in different parts of the world.[3]

This does not mean that the 'law of value' is a 'product of pre-capitalist history'. Nor does it mean that such still relatively primitive societies were burdened with the same manic pursuit of material rewards, and measurement of labour-time expenditure down to fractions of seconds, as our own; for these are, indeed, 'pure' products of bourgeois society. It only means that the embryonic forms of the 'law of value' can be discovered in the embryonic developments of commodity production, just as the 'elementary cell' of capital, the commodity, contains in an embryonic way all the inner qualities and contradictions of that social category. To deny this historical dimension of Marx's analysis is to transform the origins of capitalism into an insoluble mystery.

---

[3] Mandel, op. cit., pp. 59–65.

One could argue that this is rather a moot point for economists, interesting only for anthropologists, ethnologists or historians. But its implications are in fact extremely far-reaching. By stating that the analysis of the laws of motion governing the capitalist mode of production necessarily includes at least some essential elements of an analysis of economic phenomena valid for the whole historical epoch encompassing economic organizations in which commodity production exists, one extends the validity of parts of Marx's *Capital* not only into the past but also into the future. For phenomena of commodity production obviously survive, at least partially, in those societies in which the rule of capital has already been overthrown, but which are not yet fully-fledged classless, that is socialist, societies: the USSR and the People's Republics of Eastern Europe, China, North Vietnam, North Korea and Cuba. *Capital* is no more a guide to understanding the laws of motion of these societies than it is a guide to understanding the laws of motion of developed late medieval society based upon petty commodity production. But it can tell us a lot about the dynamics (and disintegrating logic) of commodity production and money economy in such non-capitalist societies, and the contradictions which these introduce into the specific and 'pure' laws of motion of the latter.

If *Capital* is not a treatise on eternal economic laws, does it at least contain a science of the capitalist economy? Some Marxists, in the first place the German Karl Korsch, have denied this.[4] For them – as for so many bourgeois critics of Marx – *Capital* is essentially an instrument for the revolutionary overthrow of capitalism by the proletariat. According to them, it is impossible to separate the 'scientific' content of *Capital* from its 'revolutionary' intention, as the Austro-German Marxist Rudolf Hilferding tried to do.[5] This contention overlooks a basic distinction which Marx and Engels introduced between utopian and scientific socialism. Marx remained indeed a revolutionary during the whole of his adult life after 1843. But he considered it essential to base socialism (communism) upon a scientific foundation. The scientific analysis of the capitalist mode of production was to be the cornerstone of that foundation, showing why and how capitalism created, through its own development, the economic, material and social preconditions for a society of associated producers. In that sense, Marx strove, not indeed in contradiction to, but precisely as a function of this intention, to analyse capitalism in an objective and strictly scientific way. In other words, he did not simply give vent to an aggressive hostility towards a particular form of economic organization, for reasons of revolutionary passion and compassion for the downtrodden and oppressed; nor, it hardly needs to be said, was he motivated by personal spite, material failure or psychotic imbalance. Marx sought to discover objective laws of motion. There was nobody – not even the typical bourgeois *Spiesser* – whom he despised more than the man with scientific pretensions who nevertheless deliberately twists empirical data or falsifies research results to suit some subjective purpose. Precisely because Marx was convinced that the cause of the proletariat was of decisive importance for the whole future of mankind, he wanted to create for that cause not a flimsy platform of rhetorical invective or wishful thinking, but the rock-like foundation of scientific truth.

2. THE METHOD OF *CAPITAL*

The purpose of *Capital* is itself a clear reminder of the method of knowledge applied by Marx to his main work: the method of the materialist dialectic. Marx left no doubt that this was indeed how he himself understood his labours. In a letter sent to Maurice Lachâtre, the editor of the first French edition of *Capital* Volume 1, he insisted on the fact that he was the first person to have applied this method to the study of economic problems.[6] Again in his own postface to the second German edition of *Capital* Volume 1, Marx specified this use of the dialectical method as the *differentia specifica* of *Capital*, which distinguished it from all other economic analyses.[7]

---

[6] Marx, letter to Maurice Lachâtre of 18 March 1872; see 'Preface to the French Edition', p. 104 below.

[7] See below, pp. 102–3.

When the dialectical method is applied to the study of economic problems, economic phenomena are not viewed separately from each other, by bits and pieces, but in their inner connection as an integrated totality, structured around, and by, a basic predominant mode of production. This totality is analysed in all its aspects and manifestations, as determined by certain given laws of motion, which relate also to its origins and its inevitable disappearance. These laws of motion of the given mode of production are discovered to be nothing but the unfolding of the inner contradictions of that structure, which define its very nature. The given economic structure is seen to be characterized at one and the same time by the unity of these contradictions and by their struggle, both of which determine the constant changes which it undergoes. The (quantitative) changes which constantly occur in the given mode of production, through adaptation, integration of reforms and self-defence (evolution), are distinguished from those (qualitative) changes which, by sudden leaps, produce a different structure, a new mode of production (revolution).

Marx clearly opposes his own dialectical method of investigation and knowledge to that of Hegel, although he never hesitates to recognize his debt of gratitude to the German philosopher who, spurred on by the French Revolution, catapulted dialectical thought back into the modern world. Hegel's dialectics were idealist: the basic motion was that of the Absolute Idea; material reality was only the outward appearance of ideal essence. For Marx, on the contrary, the dialectic is materialist, 'the ideal is nothing but the material world reflected in the mind of man, and translated into forms of thought'.[8] The basic laws of motion of history are those of real men, themselves producing their own material existence in a given social framework. The development of thought corresponds in the final analysis to that basic movement, and reflects it, albeit through many mediations. Thus the scientific thought process through which Marx came to understand the operations of the capitalist mode of production was itself a product of that mode of production, of bourgeois society and its contradictions. Only secondarily can it be seen as a product of the development of many human sciences and ideologies: classical German philosophy; English political economy; French historiography and political science; pre-Marxian socialism. Only the growth of bourgeois society and its contradictions, above all the struggle between capital and labour, enabled Marx to assimilate, combine and transform these sciences in the specific way and the specific direction he did. Nevertheless, while the materialist dialectic is Hegel's (idealist) dialectic 'turned right side up again', both have basic common traits. Dialectics as the logic of motion presupposes that *all* motion, *all* evolution, whether of nature, society or human thought, adopts certain general forms which are called 'dialectical'.[9] Engels and Lenin both saw, in the very way in which *Capital* Volume 1 was constructed, a striking application of this general dialectical method; thus Lenin wrote that although Marx had never written his projected short treatise on dialectics, he had nevertheless left us *Capital*, which is the application of the materialist dialectic in the field of economic phenomena.[10]

---

[8] ibid., p. 102.

Precisely because Marx's dialectic is a materialist one, however, it does not start from intuition, preconceptions or mystifying schemes, but from a full assimilation of scientific data. The method of investigation must differ from the method of exposition. Empirical facts have to be gathered first, the given state of knowledge has to be fully grasped. Only when this is achieved can a dialectical reorganization of the material be undertaken in order to understand the given totality. If this is successful, the result is a 'reproduction' in man's thought of this material totality: the capitalist mode of production.

The main danger for any scientist involved in the study of social phenomena is that of taking anything for granted, of 'problem-blindness'. The distinction between appearance and essence, which Marx inherited from Hegel[11] and which is part and parcel of the dialectical method of investigation, is nothing but a constant attempt to pierce farther and farther through successive layers of phenomena, towards laws of motion which *explain* why these phenomena evolve in a certain direction and in certain ways. Constantly searching for questions – calling into question! – where others only see ready-made answers and vulgar 'evidence': this is certainly one of Marx's main merits as a revolutionary innovator in economic science.

[9] Engels, letter to Conrad Schmidt of 1 November 1891, in Marx/Engels, *Selected Correspondence*, Moscow, 1965, p. 439.

[10] Lenin, 'Plan of Hegel's Dialectics (Logic)', *Collected Works*, Vol. 38, p. 319.

[11] 'There it will be seen what the philistine's and vulgar economist's *way of looking at things* stems from, namely, from the fact that it is only the direct *form of manifestation* of relations that is reflected in their brains and not their *inner connection*. Incidentally, if the latter were the case what need would there be of *science*?' (letter from Marx to Engels, 27 June 1867, *Selected Correspondence*, p. 191). See also *Capital*, Vol. 3, p. 307.

But for Marx, the materialist dialectician, the distinction between 'essence' and 'appearance' in no sense implies that 'appearance' is less 'real' then 'essence'. Movements of value determine in the last analysis movements of prices; but Marx the materialist would have laughed at any 'Marxist' who suggested that prices were 'unreal', because in the last analysis *determined* by value movements. The distinction between 'essence' and 'appearance' refers to different levels of determination, that is in the last analysis to the process of cognition, not to different degrees of reality. To explain the capitalist mode of production in its totality it is wholly insufficient to understand simply the 'basic essence', the 'law of value'. It is necessary to integrate 'essence' and 'appearance' through all their intermediate mediating links, to explain how and why a given 'essence' appears in given concrete forms and not in others. For these 'appearances' themselves are neither accidental nor self-evident. They pose problems, they have to be explained in their turn, and this very explanation helps to pierce through new layers of mystery and brings us again nearer to a full understanding of the specific form of economic organization which we want to understand. To deny this need to reintegrate 'essence' and 'appearance' is as un-dialectical and as mystifying as to accept 'appearances' as they are, without looking for the basic forces and contradictions which they tend to hide from the superficial and empiricist observer.

The way in which *Capital* starts with an analysis of the basic categories of commodity production, with the 'basic unit' (fundamental cell) of capitalist economic life, the commodity, has often been cited as a model application of this materialist dialectic. Marx himself makes it clear that he does not start from a basic concept – value – but from an elementary material phenomenon – the commodity – which is at the basis of capitalism, as the only economic organization based upon generalized commodity production.[12] It is therefore correct but incomplete, strictly speaking, to say that Marx's method consists of 'rising from the abstract to the concrete'.[13] In fact, he starts from elements of the material concrete to go to the theoretical abstract, which helps him then to reproduce the concrete totality in his theoretical analysis. In its full richness and deployment, the concrete is always a combination of innumerable theoretical 'abstractions'. But the material concrete, that is, real bourgeois society, exists before this whole scientific endeavour, determines it in the last instance, and remains a constant practical point of reference to test the validity of the theory. Only if the reproduction of this concrete totality in man's thought comes nearer to the real material totality is thought really scientific. At first sight, the movement which dominates *Capital* Volume 1 appears as a movement of economic 'categories', from the commodity and its inner contradictions to the accumulation of capital and its breakdown. The question has often been asked: is this movement just an abstract synopsis of the 'essence' of capitalism, or is it a greatly simplified reflection of real economic development, that is, the real history leading from the first appearance of commodity production up to full-scale capitalist production in the West, purified of all secondary and combined forms which would only obscure the basic nature of this movement?

---

[12] Karl Marx, 'Randglossen zu A. Wagners "Lehrbuch der politischen Oekonomie"', *MEW* 19, pp. 364, 368–9 (English translation in *Theoretical Practice*, No. 5, London, 1972).

It is impossible to answer this question simply with a 'yes' or a 'no'. Commodities produced accidentally in pre-capitalist societies, at the very margin of the basic processes of production and consumption, obviously cannot trigger off the striking and terrifying logic of the 'law of value' which Marx majestically unfolds in *Capital.* Commodity production as a basic and dominant feature of economic life presupposes capitalism, that is a society in which labour-power and instruments of labour have themselves become commodities. In that sense it is true that the analysis of Volume 1 of *Capital* is logical (based upon dialectical logic) and not historical.

---

[13] Marx, *Grundrisse*, Pelican Marx Library, p. 101. See on the contrary Lenin (op. cit., p. 171): 'Thought proceeding from the concrete to the abstract ... does not get away *from* the truth but comes closer to it.' In his comments on the three volumes of *Capital* written in the early thirties, D. I. Rosenberg makes the interesting point that Marx's abstractions are in their turn concrete, inasmuch as they are related to a concrete economic formation and as they are historically determined. They are neither arbitrary nor *a priori* abstractions. (See the Spanish translation of the original Russian text, published by *Seminario de 'El Capital'*, Escuela Nacional de Economia, UNAM, Mexico, Cuaderno I, p. 46.)

But dialectics imply that every phenomenon has an origin and an end, that nothing is either eternal or finished once and for all. Hence the historical cell of capital is at the same time the key to the logical analysis of capital: phylogenesis and embryology cannot be completely separated. Within capital accumulation in contemporary everyday capitalist life, some aspects of primitive capital accumulation are reproduced: without that primitive capital accumulation, there would be no capitalist mode of production. So the logical analysis does reflect some basic trends of historical development after all. The simplest forms of appearance of the 'economic categories' (which are just forms of material existence, of material reality as perceived and simplified by the human mind) are often also their primitive, that is their original, form. However controversial this interpretation may be, it is difficult to deny that this unity of historical and logical analysis is the way in which Marx and Engels understood their own method.[14]

A whole literature has been produced, from Bernstein to Popper and on to contemporary academic economists, on the subject of the 'useless', 'metaphysical' or even 'mystifying' nature of the dialectical method which Marx borrowed from Hegel.[15] The positivist narrowness of outlook of these critics themselves generally bears eloquent testimony to the contrary, that is to the broad historical vision and the piercing lucidity which the dialectical method helped Marx to achieve. Thanks to that method, Marx's *Capital* appears as a giant compared to any subsequent or contemporary work of economic analysis. It was never intended as a handbook to help governments to solve such problems as balance-of-payments deficits, nor yet as a learned, if somewhat trite, explanation of all the exciting happenings in the market place when

Mr Smith finds no buyer for the last of his 1,000 tons of iron. It was intended as an explanation of what would happen to labour, machinery, technology, the size of enterprises, the social structure of the population, the discontinuity of economic growth, and the relations between workers and work, as the capitalist mode of production unfolded all its terrifying potential. From that point of view, the achievement is truly impressive. It is precisely because of Marx's capacity to discover the long-term laws of motion of the capitalist mode of production in its essence, irrespective of thousands of 'impurities' and of secondary aspects, that his long-term predictions – the laws of accumulation of capital, stepped-up technological progress, accelerated increase in the productivity and intensity of labour, growing concentration and centralization of capital, transformation of the great majority of economically active people into sellers of labour-power, declining rate of profit, increased rate of surplus value, periodically recurrent recessions, inevitable class struggle between Capital and Labour, increasing revolutionary attempts to overthrow capitalism – have been so strikingly confirmed by history.[16]

This judgement has generally been challenged on two grounds. The easiest way out for critics of Marx is simply to deny that the laws of motion of the capitalist mode of production which he discovered have been verified at all. This is generally done by reducing them to a couple of misstated and oversimplified formulae (see below): 'progressive immiseration of the working class' and 'ever-worsening economic crisis'.[17] A more sophisticated objection was advanced by Karl Popper, who denied the very possibility, or rather the scientific nature, of such 'laws', calling them 'unconditional historical prophecies' to be clearly distinguished from 'scientific predictions'. 'Ordinary predictions in science,' says Popper, 'are conditional. They assert that certain changes (say, of the temperature of water in a kettle) will be accompanied by other changes (say the boiling of the water).'[18] Popper denies the scientific nature of *Capital* by asserting that, unlike scientific theories, its hypotheses cannot be scientifically tested.[19]

---

[16] 'However important these technical contributions to the progress of economic theory in the present-day appraisal of Marxian achievements, they are overshadowed by his brilliant analysis of the long-term tendencies of the capitalist system. The record is indeed impressive: increasing concentration of wealth, rapid elimination of small and medium-sized enterprise, progressive limitation of competition, incessant technological progress accompanied by the ever-growing importance of fixed capital, and, last but not least, the undiminishing amplitude of recurrent business cycles – an unsurpassed series of prognostications fulfilled, against which modern economic theory with all its refinements has little to show indeed.' (Leontief, op. cit., p. 94.)

[17] A classical example of such over simplification is given by Paul Samuelson. He reduces the laws of motion of the capitalist mode of production to two (!): 'the i miseration of the working class', and 'the growing monopolization under capitalism', and concludes on the first that 'it simply never took place', while declaring on the second that 'for thirty years Marx seemed to have been right in this prophecy, even though for the next seventy years he does not seem to be borne out by the most careful researches on industrial

This is obviously based upon a misunderstanding of the very nature of the materialist dialectic, which, as Lenin pointed out, requires constant verification through praxis to increase its cognition content.[20] In fact, it would be very easy to 'prove' Marx's analysis to have been wrong, if experience had shown, for example, that the more capitalist industry develops, the smaller and smaller the average factory becomes, the less it depends upon new technology, the more its capital is supplied by the workers themselves, the more workers become owners of their factories, the less the part of wages taken by consumer goods becomes (and the greater becomes the part of wages used for buying the workers' own means of production). If, in addition, there had been decades without economic fluctuations and a full-scale disappearance of trade unions and employers' associations (all flowing from the disappearance of contradictions between Capital and Labour, inasmuch as workers increasingly become the controllers of their own means and conditions of production), then one could indeed say that *Capital* was so much rubbish and had dismally failed to predict what would happen in the real capitalist world a century after its publication. It is sufficient to compare the real history of the

---

concentration'. Everything is then capped by the final statement that Marx thought there was an 'inevitable law of capitalist development that the business cycle should be getting worse and worse' and that this was not true either (Paul A. Samuelson, 'Marxian Economics as Economics', *American Economic Review*, Vol. 57 (1967), pp. 622-3).

period since 1867 on the one hand with what Marx predicted it would be, and on the other with any such alternative 'laws of motion', to understand how remarkable indeed was Marx's theoretical achievement and how strongly it stands up against the experimental test of history.[21]

3. THE PLAN OF *CAPITAL*

Capital was not the result of spontaneous generation nor was it the product of a sudden interest of Marx in economic problems. Ever since this doctor in philosophy (Jena, 1841) had become a communist in the course of the eighteen-forties under the pressure of current experience with social problems (the treatment of wood-thieves in the Rhine provinces of Prussia; the uprising of the Silesian textile workers; the strikes in England; the class struggle in France), he had turned towards economic studies. But his first encounter with modern political economy (which left its main results in the *Economic and Philosophical Manuscripts, The Poverty of Philosophy, Wage Labour and Capital* and *The Communist Manifesto*) was roughly interrupted by the pressure of external events. Participating actively in politics, Marx returned from Paris to Germany at the outbreak of the revolutionary movement in 1848. There he founded and directed a daily paper. When counter-revolutionary reaction submerged Europe after the revolutions collapsed, he emigrated to London and had to struggle for his livelihood as a journalist. These current pressures, together with the burden of émigré politics in London, delayed the possibility of a systematic presentation of his economic theory for a whole decade.

---

[21] An amusing aside to this seemingly absurd hypothesis of 'other' imaginable laws of motion is provided by Vilfredo Pareto's 'critique' of Marx's theory of value. In order to prove that Marx had a built-in *petitio principis* in the labour theory of value, Pareto stated that we might as well assume that the seamstress hires her machine, and her own subsistence, which would then lead to the conclusion that the machine has 'produced' the surplus-value ('Introduction à K. Marx *Le Capital*, extraits faits par P. Lafargue', in *Marxisme et économie pure*, Geneva, 1966, pp. 47–8). Leaving aside the fact that his example 'proves' nothing of the kind, it is significant what this counter-model implies: that workers hire their own means of production and, as a result of this, *own the products of their labour*, sell them on the market, and thereby appropriate the profits (surplus-value) produced in the course of the process of production. Now it is evident that this has in no way been the predominant trend of industrial development in the last 150 years. But, even at the end of the nineteenth century, the question seemed so 'open' in Pareto's mind that he could advance such an hypothesis without being struck by its evident absurdity. This all the more underlines the profundity of Marx's insight into the operations of capitalism.

Only when, through Lassalle, a publisher pressed him to explain his economic ideas in a fully-fledged way did he return to a full-scale encounter with Adam Smith and Malthus, Ricardo and J.-B. Say, Simonde de Sismondi and Tooke, together with the famous British government *Blue Books* which were to become an invaluable source of factual material about the conditions of British industry, trade, finance and working-class life. The systematic study of economic facts and thoughts about capitalism, resumed by Marx around 1857, produced the following works:

(a) a first rough draft of *Capital*, published posthumously under the title *Grundrisse der Kritik der politischen Oekonomie* (Foundations of the Critique of Political Economy), written in 1857–8;
(b) the uncompleted book *Zur Kritik der politischen Oekonomie* (A Contribution to the Critique of Political Economy), published in 1859;
(c) the 1861–3 manuscripts, twenty-three enormous notebooks, from which Kautsky extracted *Theories of Surplus-Value* (also known as Volume 4 of *Capital*). This however encompasses only notebooks VI–XV inclusive. Notebooks I–V deal with matters generally encompassed in *Capital* Volume 1; notebooks XVI, XVII and XVIII deal with matters in *Capital* Volume 3; notebooks XIX–XXIII again deal with matters related to *Capital* Volume 1, and include a lengthy treatment of the history of techniques and the use of machines under capitalism;
(d) a manuscript of 1864–5, mostly dealing with matters taken up in *Capital* Volume 3;
(e) four manuscripts written between 1865 and 1870, from which Engels extracted most of the material for *Capital* Volume 2;
(f) the final version of *Capital* Volume 1, written in 1866–7.

Of the six basic economic writings of the mature Marx, Volume 1 is therefore the only one which the author completed and edited himself, and of which he even made available corrected editions in German and in French.[22] Volumes 2 and 3 of *Capital*, left unfinished, were posthumously and laboriously published by Marx's life-long friend Friedrich Engels. *Theories of Surplus-Value* was rearranged and published by Kautsky. The *Grundrisse* was presented to the public for the first time only in 1939. A considerable part of the 1861–3 manuscripts still remains unpublished.

---

[22] The two most accurate, scientific editions of *Capital* Vol. 1 are that of the Institute for Marxism-Leninism of the Central Committee of the SED (*MEW* 23) and that of H. J. Lieber and Benedikt Kautsky (Stuttgart, 1962), both of which indicate the variations of the text between the various German editions and the French edition edited by Marx and Engels themselves. The

The initial plan of *Capital* was drawn up in 1857; the final plan dates from 1865–6. Between these two dates there lay nine years of intense study, especially in the British Museum, realized under very difficult circumstances. Marx was burdened by constant financial troubles; by the illness and death of three of his children, among them his beloved son Edgar; and by his growing re-involvement in current political and social studies, especially through his activity in the International Working Men's Association (the so-called First International). The need to answer a sharp and slanderous attack by a German political opponent, a certain Herr Vogt, cost Marx nearly half a year's delay in the production of *Capital* Volume 1. Finally, illness and bad health became increasing obstacles. He himself spoke sarcastically of his 'carbuncles', the effects of which the bourgeoisie would not forget for a long time. But in fact it is his strikingly stoical attitude towards all the miseries surrounding him, rather than any special bitterness born from material hardship, that permeates his mature work.

From the beginning, Marx wanted to present an all-round analysis of capitalism in its totality. The initial plan of *Capital* already bears witness to this intention and reads as follows:

1. *Volume on Capital*
   (a) Capital in general
      (1) Process of production of capital
      (2) Process of circulation of capital
      (3) Profit and interest
   (b) On competition
   (c) On credit
   (d) On joint stock companies
2. *Volume on landed property*

Lieber edition is somewhat more complete, because it indicates all these variations in the text itself. I have counted at least one hundred textual variations in the Lieber edition, some of which are important, but only a few sufficiently so to be mentioned in this introduction. [The present translation was made from *MEW* 23. Significant divergences between this and the earlier editions in German and French are indicated in the text.]

3. *Volume on wage labour*
4. *Volume on the State*
5. *Volume on international trade*
6. *Volume on the world market and crises*[23]

The 1865–6 version of *Capital*, however, falls into four volumes:

Volume 1: Process of production of capital
Volume 2: Process of circulation of capital
Volume 3: Forms of the process in its totality
Volume 4: History of the theory

Roman Rosdolsky, who has made the most extensive study to date of this problem, has isolated no less than fourteen different versions of the plan for *Capital* between September 1857 and April 1868.[24]

Two questions are raised by these changes. First, why did Marx modify his initial plan, and what implications do the modifications have for an understanding of Marx's method and for the content of *Capital*? Second, does the 1865–6 version imply that the four volumes which we possess today represent the full – although in the case of all save the first volume unedited – work as finally intended by Marx? The answer to each of those questions has many interesting implications both for the discussion of Marx's economic theory itself and for the light it throws on the contributions made by some of his gifted followers and disciples.

In fact, what we today call *Capital* is the third attempt by Marx to present his views on the capitalist mode of production in its totality. The first attempt, the *Grundrisse* of 1857–8, follows exactly the initial plan of *Capital*, but stops at point 1 (a) (3) of that plan. The second attempt, dating from 1861–3, is still unpublished, except for the part on *Theories of Surplus-Value*. The third attempt is the 1865–6 one, of which we have Volumes 1–4. We know that, as early as January 1863, Marx had already decided to deal with land rent as an element of distribution of total surplus-value among different sectors of the ruling classes. However, he still seemed to stick at that time to a separate volume on wage-labour, a separate volume on landed property, and separate volumes on credit, competition and joint-stock companies.[25] The logic of this plan implied the desire to deal with the basic social classes of bourgeois society in a separate way: first the industrial capitalists; then the landowners; finally the proletariat. It implied also the desire to separate sharply the problems of production of value, surplus-value and capital from the problems of capitalist competition, which can only be understood as arising out of processes of redistribution of previously produced surplus-value.

---

[23] Karl Marx, letter to Engels of 2 April 1858, in *Selected Correspondence*, p. 104.

[24] Roman Rosdolsky, *Zur Entstehungsgeschichte des Marx'schen Kapital*, Frankfurt, 1968, Vol. 1, p. 78.

However, if this original plan was clearly a necessary stepping stone towards the final analysis of the capitalist mode of production, as Marx's analysis progressed it proved itself increasingly an obstacle to a rigorous and consistent *exposé* of the laws of motion of that mode of production. It had therefore to be discarded in the end. The volume on wage-labour became integrated into Volume 1, 'The Process of Production of Capital'. It appeared impossible to deal with wage-labour separately and apart from the production of surplus-value, that is from the capitalist process of production (Marx probably intended to deal with the fluctuations of wages in Volume 6 on the world market and crises). The volume on landed property became integrated, together with those on profit and interest, on competition and on joint-stock companies, into the new Volume 3, which examines key forms of the capitalist mode of production in its totality, from the point of view of redistribution of the total surplus-value produced among various sectors of the propertied class.

Looking at this transformation of the initial plan of *Capital*, we can, however, also understand what did *not* change. Volumes 1 and 2 of *Capital* can still be subsumed under the heading of 'Capital in General'. Only Volume 3, like the originally planned 4, 5 and 6, which were never written, falls under the heading of 'many capitals'. This means concretely that a certain number of problems, such as, for instance, the problem of the origin and mechanics of the 'trade cycle' (of capitalist crises of overproduction), have no place in Volumes 1 and 2 and can be dealt with only when one descends from the highest level of abstraction, where capital is dealt with in its global relationship to wage-labour, to an examination of the interactions of various capitals upon each other. Because she did not take this specific structure of the successive volumes of *Capital* into account, Rosa Luxemburg was methodologically mistaken in accusing Marx of having constructed his reproduction schemes of Volume 2 without solving the 'realization problem' or without formulating a theory of crises.[26] I shall return to this interesting problem in my introduction to *Capital* Volume 2.

---

[25] Karl Marx, letter to Kugelmann of 28 December 1862, *MEW* 30, pp. 639–40; *Theories of Surplus-Value*, London, 1969, Part One, p. 404.

A similar mistake is made by Joan Robinson, in her Preface to the second edition of *An Essay on Marxian Economics*, where she construes a contradiction between the assumptions regarding real wages of *Capital* Volume 1 and those of Volume 3. In Volume 1, she says, Marx assumes that a rising labour productivity leads to a rising rate of exploitation, whereas in Volume 3 he assumes that rising labour productivity could lead, through a stable rate of exploitation, to a rising rate of real wages and a declining rate of profit.[27] Joan Robinson does not understand that Volumes 1 and 3 of *Capital* are at different levels of abstraction, deal with different questions, and make different assumptions in order to clarify the *specific dynamics* which allow answers to these questions.

In Volume 1, Marx examines the relations between Capital and Labour in general, abstracting from the effects of competition between capitalists on the distribution of surplus-value and on the variations of real wages. He therefore assumes initially stable real subsistence wages, in order to show through what mechanics surplus-value is produced, appropriated and increased by capital. In Volume 3 he examines the effects of capitalist competition upon the distribution and redistribution of surplus-value among capitalists, and therefore has to integrate into the analysis the effects of this competition on the rate of exploitation (for example in periods of boom, with a high level of employment). In order to work out the basic answers to these questions, it is perfectly logical to abstract *initially* from fluctuations in the rate of profit and wages in Volume 1, and to assume *initially* a stable rate of exploitation in Volume 3, but subsequently to abandon these simplifying hypotheses (Volume 1, Chapter 17; Volume 3, Chapter 14).

Finally, it seems clear from many remarks interspersed throughout the manuscript of Volume 3 that Marx maintained his intention of completing *Capital* with volumes on the state, foreign trade, the world market and crises, although he placed these problems

[26] Rosa Luxemburg, *The Accumulation of Capital*, London, 1956, pp. 329–47; Rosdolsky, op. cit., Vol. 1, pp. 86–97.

[27] Joan Robinson, *An Essay on Marxian Economics*, London, 1949, pp. viii–ix.

clearly outside the final plan of *Capital* itself.[28] Only when the unpublished manuscript of 1861–3 becomes available will we know whether some rough draft of what he intended to develop in these three books does indeed exist somewhere, or whether it was intended as a completely new and further development of his study of bourgeois society.

In view of these changes in the plan of *Capital* as a whole, the final version of the plan of Volume 1 is all the more striking. We should not forget that Volume 1, as edited by Marx, is largely *posterior* to the original and incomplete drafts of Volumes 2 and 3 later to be edited by Engels.[29] It is therefore Volume 1 which allows us the best insight into Marx's view of capitalism.

From the place of Volume 1 in the total final plan of *Capital*, we can immediately draw an answer to two misconceptions which occur again and again in discussion of Marx's economic theory. It is true that according to Marx and Engels capitalists do not exchange the commodities they own on the basis of their value, whereas under petty commodity production exchange of commodities is roughly based upon their value.[30] But it does not follow at all that *Capital* Volume 1, which assumes the exchange of commodities according to their value, is concerned with pre-capitalist commodity production and exchange, and that only in Volume 3 do we start to examine what capitalist commodity circulation is all about. On the contrary, Marx abstracts from the problem of redistribution of surplus-value among competing capitalists – that is, the problem of the equalization of the rate of profit – in Volume 1 precisely in order to isolate and demonstrate the laws of *capitalist* commodity production and circulation in their 'purest', most fundamental way.

In the same way it is wrong to assume that Volume 1 deals only with the 'essence' or with 'abstractions', whereas 'concrete' capitalism is analysed only in Volume 3. Nothing could be more 'concrete' and closer to immediately perceived economic data ('appearances') than the analysis of the working day, of wages and of machinery in Volume 1. Commentators here confuse the *type of question* solved in Volume 1 with the *method of answering.* Volume 1 abstracts from capitalist competition, from uneven and combined development and *therefore* from prices of production and equalization of the rate of profit and even more from market prices, in order to reveal the *basic* origin of surplus-value in the process of production, which is a process of consumption of labour-power by capital. But this problem is dealt with by a combination of theoretical insight and empirical verification, by a constant attempt to discover the mediating links between 'essence' and 'appearance', by a thorough analysis of how and why the 'essence' (the value of labour-power) is manifesting itself through the 'appearances' (the fluctuations of real wages).

[28] Karl Marx, *Capital*, Vol. 3, pp. 232, 392, etc.; Rosdolsky, op. cit., Vol. 1, p. 76.

[29] According to Maximilien Rubel, the manuscripts for *Capital* Vol. 2 originated between 1865 and 1870, apart from a new version of the first four chapters written in 1877 and a short manuscript of 1879; the manuscripts for Vol. 3 date from 1861–3 and 1865–70 (*Bibliographie des œuvres de Karl Marx*, Paris, 1956, p. 22). We are therefore justified in assuming that, except for the short passages changed in 1877 and 1879, the manuscripts used for editing Vol. 2 and 3 of *Capital* are anterior to the final version of Vol. 1. (See also Engels' introduction to Vol. 2, *MEW* 24, pp. 8–13.)

4. THE PLAN OF VOLUME I

Volume 1 of *Capital* presents itself as a rigorously logical construction. We start from the elementary form of capitalist wealth – the commodity – and its inner contradiction – the contradiction between use-value and exchange-value. Because it is produced by *private* labour, whose social character can no longer be recognized automatically, immediately and directly by society, the commodity can exist only together with a necessary corollary, money, a universal means of exchange. But the analysis of the circulation of commodities accompanied by circulation of money leads to the unfolding of the inner potentialities and contradictions of money: the possibility of exchange-value embodied in money becoming an autonomous economic agent; of money appearing as starting and final point, and not simply intermediary, of a process of circulation; of money bent upon accretion of money, that is of capital.

In pre-capitalist societies, capital appears outside the sphere of production, and hardly ever enters that sphere. It feeds parasitically upon the social surplus product produced and originally appropriated by non-capitalist classes. Here Marx comes to his central point. A basic difference between the capitalist and pre-capitalist modes of production is that under capitalism capital not only appropriates surplus-value; it produces surplus-value. Because he considered this fundamental to an understanding of all aspects of bourgeois society – incidentally, not only the economic but also the political – Marx starts *Capital* with a whole volume devoted to a lengthy analysis of the process of production. For the capitalist process of production is at one and the same time a process of production of value, a process of production of surplus-value, a process of production of capital, and a process of production and constant reproduction of the basic antagonistic social relations: the relation between wage-labour and capital, the compulsion for the proletariat to sell its labour-power to the capitalists, the compulsion for the capitalists to accumulate capital and therefore to maximize the extortion of surplus-value from the workers.

Volume 1 of *Capital* is centred around Marx's basic discovery, the explanation of the 'secret' of surplus-value. There exists one commodity, to wit labour-power, whose use-value for the capitalist is its ability to produce new value larger than its own exchange-value. The 'process of production' which Marx analyses in Volume 1 is, therefore, essentially the process of production of surplus-value.

The production of surplus-value can, however, be examined in a more detailed way only if capital itself is subdivided into constant capital and variable capital. *Constant capital* represents that part of the wealth of the capitalist class with which it acquires and maintains a monopoly of property and access to the material means of production. Thereby it cuts the working class off from any possibility of producing its own livelihood in an independent way. It is a necessary precondition for the production of surplus-value. But it does not produce that surplus-value in and by itself. Only the labour-power of living labour produces additional value, including surplus-value. That is why Marx calls that portion of capital by which the capitalists buy the labour-power of the workers *variable capital*, for only that portion actually produces surplus-value.

The next step in the analysis is the distinction between the production of absolute and of relative surplus-value. Absolute surplus-value is produced by a lengthening of the working day beyond that number of hours during which the worker produces the value which is only the equivalent of his wages. Relative surplus-value is produced by increasing the productivity of labour in the wage-goods industry sector, which enables the worker to reproduce the equivalent of his wages in a shorter portion of the working day, thereby increasing surplus-value without a lengthening of the working day. Marx notes that while the production of absolute surplus-value predominated in the early centuries of the capitalist mode of production (in England, roughly speaking, between the sixteenth century and the first half of the nineteenth), the production of relative surplus-value becomes predominant once the logic of the industrial revolution (of the development of machinery) and the logic of the class struggle between labour and capital fully unfold themselves.

A central section of Part Four of Volume 1 ('The Production of Relative Surplus-Value') is taken up by a lengthy and minute analysis of manufacture and of the modern factory (Chapters 14 and 15). Here the production of surplus-value takes on an important additional dimension. During the stage of manufacturing industry, capital exploits the fruits of an increase in the productivity of labour born from more and more advanced forms of the division of labour. But the *technique of production* remains fundamentally the same. Labour is subdivided in function of the subdivision of the final product produced by manufacture. But beyond these subdivisions no changes occur in the labour process. The main interest for the capitalist during the stage of manufacture is, therefore, the constant direct *control of capital over labour* in order to secure a maximum expenditure of surplus labour with a given level of technique. It is like a workhouse in which the workers lose their freedom to determine their own work rhythm, in which work becomes unfree, forced labour from that point of view also. Many initial manufacturing concerns were indeed literally that: workhouses, filled with labourers who to various degrees had lost their individual freedom.

With the industrial revolution and the emergence of the modern factory, this process of the submission of labour to capital in the course of the process of production is rooted, not only in the hierarchical forms of labour organization, but in the very nature of the production process itself. Inasmuch as production becomes mechanized, it becomes reorganized around machinery. The work rhythm and work content of living labour are subordinated to the mechanical needs of machinery itself. Alienation of labour is no longer only alienation of the products of labour, but alienation of the forms and contents of the work itself.

The explosive potentialities of modern machinery are developed by Marx in three directions simultaneously. Machines are capital's main weapon for subordinating labour to capital in the course of the process of production. Machines are the main weapon for increasing the production of relative surplus-value, thereby relentlessly spurring on the process of accumulation of capital. And labour-saving machines are the main weapon for producing and reproducing the industrial 'reserve army of labour', through which wages are kept fluctuating around the value of the commodity labour-power, and through which the appropriation of surplus-value is normally guaranteed to the capitalists.

Marx, therefore, logically integrates the development of the class struggle between capital and labour into his analysis of the production of surplus-value, inasmuch as he sees that class struggle as originating in that process of production. The extortion of surplus-value from living labour means a struggle by the capitalists to lengthen the working day, to increase the work-load of the workers without increasing wages, to appropriate for capital all the benefits of increased productivity of labour. Conversely, the struggle against capitalist exploitation means, for the workers, a struggle to reduce the working day without any reduction of wages, a struggle for cuts in the work-load, a struggle for increased real wages. How this class struggle against the immediate aspects of capitalist exploitation transforms itself into a struggle for the overthrow of the capitalist system – this question is briefly taken up in the eighth and final part of Volume 1. Part Seven, meanwhile, deals basically with the accumulation of capital, the goal of the whole infernal logic which Marx has laid bare so far. Capital produces surplus-value which in turn is, to a large extent, transformed into additional capital, which in turn produces additional surplus-value. And so on, with all its subsequent contradictory effects for mankind.

If we list the contents of the successive parts of Volume 1, subdividing Part One into its three constituent chapters, we can see how this flawless logic of the analysis unfolds and how it roughly corresponds to the historical process 'stripped of the historical form and diverting chance occurrences'.[31]

I. Starting point: elementary form of capitalist wealth: the commodity

---

[31] Friedrich Engels' review of Marx's *A Contribution to the Critique of Political Economy*. See appendix to volume of that name, London, 1971, p. 225.

(a) the commodity and the realization of its exchange-value, or the process of exchange
(b) the process of exchange and the means of exchange: money
(c) money, necessary mediator of the process of circulation of commodities
II. Money transforming itself into capital, i.e. value searching for an accretion of value, surplus-value; the nature of surplus-value
III. The production of surplus-value: absolute surplus-value
IV. The production of surplus-value: relative surplus-value (from manufacturing to the modern factory system)
V. Relations between wages, productivity of labour and surplus-value; the rate of surplus-value
VI. How the value of labour-power is transformed into wages, their different forms and variations
VII./VIII. The accumulation of capital, i.e. capitalist wealth in its totality: its consequences for labour. The origins of capitalism (the 'primitive accumulation of capital')

At the end of Volume 1 we are back where we started from: capitalist wealth. But now we no longer understand it simply as a sum of 'elementary elements', a mountain of commodities (although it is this mountain also!). We see it now also as the result of a gigantic process of value *production*, of surplus-value *extraction*, out of living labour; as a gigantic movement constantly revolutionizing the means of production, the organization of production, the labour process and the producers themselves. The formula 'capital-value in search of additional value' is now understood as capital organizing a process of self-valorization (*Verwertung*), a process of constant searching for increases in its own value through the unity of the labour process and the process of production of increased value (*Einheit von Arbeitsprozess und Verwertungsprozess*). We thus understand more fully why an analysis of capitalism *has* first to clarify everything which happens in the course of the process of production.[32]

---

[32] The Pelican Marx Library edition of the *Grundrisse* contains a grave and regrettable error of translation. Marx's concept of *Verwertung* (valorization, process of accretion of value) is translated throughout as 'realization of capital'. Marx uses the concept of realization generally only in relation to the realization of the value of commodities (containing, of course, surplus-value). But this problem has its place in the realm of the circulation of commodities and capital, whereas the problem of valorization of capital (the problem of surplus-value or profit in relation to, or as a proportion of, capital) is a basic aspect of the capitalist process of production.

Marx's attitude towards technology, machinery and the factory system has often been misinterpreted, even by authors favourably inclined towards him. It is obviously true that more than any other contemporary economist, sociologist or philosopher, he was aware of the long-range revolutionary effects of machinery upon all aspects of life in bourgeois society. It is also true that his indictment of the inhuman results of the capitalist use of machinery cannot escape anyone who reads Chapters 10, 15 and 25 of *Capital* Volume 1 with a minimum of attention. Is it therefore appropriate to see in Marx a latter-day Luddite, a forerunner of the zero-growth prophets? Or is it true, as others have argued,[33] that Marx was a deep admirer of capitalist technology and put all his hopes in the long-run emancipatory effects of that technology, alone capable of reducing the unavoidable work-load and work-fatigue to which man is condemned?

Marx the dialectician, bent upon an all-sided analysis of capitalism and capitalist technology, avoids both these pitfalls, the conservatively romantic as well as the inhumanly mechanistic one. In classic passages of the *Grundrisse*[34] he underlines the civilizing and progressive aspects of capitalism, its giant impulse to develop the social forces of production, its relentless search for new ways and means to economize on labour, for new needs and new sectors of mass production, which help to unfold man's unlimited possibilities. But simultaneously he shows how the *specific capitalist form* of this development increases tenfold the inhuman potentiality of technology, machinery and exchange-value 'gone mad' (that is, becoming goals in themselves). Capitalism subordinates men to machines instead of using machines to liberate men from the burden of mechanical and repetitive work. It subordinates all social activities to the imperatives of an incessant drive for individual enrichment in terms of money, instead of gearing social life to the development of rich individualities and their social relations. The contradiction between use-value and exchange-value, inherent in every commodity, fully unfolds itself in this contradictory nature of *capitalist* machinery. When capitalism is not overthrown once it has created the material and social preconditions for a classless society of associated producers, this contradiction implies the possibility of a steadily increasing *transformation of the forces of production into forces of destruction*, in the most literal sense of the word: not only forces of destruction of wealth (crises and wars), of human wealth and human happiness, but also forces of destruction of life *tout court*.

5. THE MARXIST LABOUR THEORY OF VALUE

No part of Marx's theory has been more assaulted in the academic world during the last seventy-five years than his theory of value. His bourgeois critics show a sharp class instinct here, for this theory is indeed the corner-stone of the whole system. But no contemporary intellectual endeavour has been so obviously based upon a basic misunderstanding as the repeated attacks on the Marxist labour theory of value.[35]

That theory recognizes two aspects of the problem of value, a quantitative and a qualitative one. From a quantitative point of view, the value of a commodity is the quantity of simple labour (skilled labour being reduced to simple labour through a given coefficient) socially necessary for its production (that is, at a given average productivity of labour). From a qualitative point of view, the value of a commodity is determined by *abstract* human labour – commodities which have been produced by *private* labour become commensurate only inasmuch as society abstracts from the concrete and specific aspect of each individual private craft or branch of industry and equalizes all these labours as abstract social labour, regardless of the specific use-value of each commodity.

In order to understand this theory, it is sufficient to formulate the question to which Marx tried to give an answer. The problem is as follows. Man has to work in order to satisfy his material needs, to 'produce his material life'. The way in which the labour of all producers in a given society is divided among different branches of material production will determine the extent to which different needs can be fulfilled. Hence, given a certain set of needs, a rough equilibrium between needs and output requires a distribution of labour (of 'labour inputs') between these various branches of production in a given proportion, and in that only. In a primitive society, or in a fully developed socialist one, this distribution of labour inputs occurs in a consciously planned way: in a primitive society, on the basis of habits, custom, tradition, magico-ritual processes, decisions by elders etc.; in a socialist one, on the basis of a democratic selection of priorities by the mass of the associated producers-consumers themselves. But under capitalism, where labour has become private labour, where products of labour are commodities produced independently from each other by thousands of independent firms, no conscious decision pre-establishes such an equilibrium of inputs of labour and socially recognized needs (under capitalism this implies, of course, that only those needs expressed through effective demand are socially recognized). Equilibrium is reached only accidentally, through the operation of blind market forces. Price fluctuations, to which academic economists remain glued, are in the most favourable hypothesis only signals which indicate whether this equilibrium is being shaken, by what pressure and in what direction. They do not explain *what* is being equilibrated and *which* is the driving force behind all these myriad fluctuations. It is precisely this question which Marx tried to answer with his perfected labour theory of value.

---

[35] The 'classical' attack by Böhm-Bawerk was answered by Hilferding (both are printed together in Böhm-Bawerk, op. cit.). Other similar attacks were made by Pareto (op. cit., pp. 40 ff.), Michael von Tugan-Baranovsky (*Theoretische Grundlagen des Marxismus*, Leipzig, 1905, pp. 139 ff.), and others. A more recent one is contained in Joan Robinson, op. cit., and is effectively answered by Rosdolsky, op. cit., Vol. 2, pp. 626–40.

From this approach it is immediately clear that, contrary to what so many of his critics starting with the Austrian Böhm-Bawerk assumed, Marx never intended to explain short-term price fluctuations on the market with his theory of value.[36] (Probably he intended to raise some of the problems involved in short-term price fluctuations in the never-written Volume 6 of the original plan for *Capital.*) Nor does it make any sense to speak of the labour theory of value, as explained in Volume 1 of *Capital*, as a 'micro-economic theory' allegedly in contrast with the 'macro-economic' labour theory of value in Volume 3. What Marx tried to discover was a *hidden key behind price fluctuations*, the atoms inside the molecule so to speak. He moved the whole economic analysis to a different and higher level of abstraction. His question was not: *how does* Sammy run (what movements do his legs and body make while running), but *what makes* Sammy run.

It follows that 99 per cent of the criticism directed against the

---

[36] Böhm-Bawerk, op. cit., pp. 29–30; Samuelson, op. cit., p. 620; Tugan-Baranovsky, op. cit., p. 141.

Marxist labour theory of value is entirely beside the point, especially when it tries to 'refute' the first pages of Chapter 1 of *Capital* Volume 1, which have sometimes been construed as a 'proof' of that theory.[37] To say that commodities have qualities in common other than the fact that they are products of social labour transforms an analysis of social relations into a logical parlour game. Obviously, these 'other qualities' have nothing to do with the *nexus* between members of society in an anarchic market economy. The fact that both bread and aeroplanes are 'scarce' does not make them commensurable. Even when thousands of people are dying of hunger, and the 'intensity of need' for bread is certainly a thousand times greater than the 'intensity of need' for aeroplanes, the first commodity will remain immensely cheaper than the second, because much less socially necessary labour has been spent on its production.

The question has often been asked: why bother at all with this type of inquiry? Why can one not restrict 'economics' to the analysis of what actually occurs in day-to-day economic life (under capitalism, it goes without saying) – the ups and downs of prices, wages, interest rates, profits etc., instead of trying to discover mysterious 'forces beneath the surface of the economy' which are supposed to govern actual economic events, but only on a very high level of abstraction and in the very final analysis?

This neo-positivist approach is curiously and typically unscientific. Nobody dealing with medicine, not to speak of other physical sciences, would dare for fear of becoming a laughing stock to ask: 'Why bother to look for the "deeper causes" of diseases, when one can collect symptoms to establish a diagnosis?' Obviously no real understanding of economic development is possible if one does not try to discover precisely what 'lies behind' immediate appearances. Laws about immediate short-term fluctuations of prices on the market cannot explain why, to give an interesting example, one kilogram of gold buys in 1974 nearly twice as many given baskets of American consumer commodities as seventy years ago (the average consumer price index has risen somewhat more than fivefold compared to 1904, whereas the price of gold on the free market has risen nine times). Obviously this basic movement of prices in the long run has something to do with the different dynamics of the long-term social productivity of labour in the various consumer industries on the one hand and in the gold-mining industry on the other; that is, with the laws of value as formulated by Marx.

---

[37] Böhm-Bawerk, op. cit., pp. 65–80; Joseph Schumpeter, *Capitalism, Socialism and Democracy*, London, 1962, pp. 23–4.

Once we understand that the famous 'invisible hand' which is supposed to regulate supply and demand on the market is nothing but the operation of that same law of value, we can tie together a whole series of economic processes which otherwise remain disconnected pieces of analysis. Money born out of exchange can serve as a universal equivalent of the value of commodities only because it is itself a commodity with its own intrinsic value (or, in the case of paper money, represents a commodity with its own intrinsic value). Monetary theory is re-united with the theory of value and the theory of capital accumulation. The ups and downs of the trade cycle appear as the mechanism through which upheavals in the value of commodities end by asserting themselves, with the painful devalorization (loss of value) this entails, not only for the 'infantry' of the commodity army, the individual mass of finished consumer goods sold on a day-to-day basis, but also for its 'heavy artillery', that is, large-scale machinery, fixed capital. The theory of economic growth, of the 'trade cycle', of capitalist crises, the theory of the rate of profit and of its tendency to decline – everything flows in the last analysis from this operation of the law of value. So the question whether it has any use at all in economic analysis is, therefore, as meaningless as the question whether you need the concept of basic particles (atoms, etc.) in physics. Indeed, no coherent and consistent analysis of the capitalist economy in its totality, explaining all the basic laws of motion of that system, is possible without 'elementary principles' organized around the value of commodities.

In Marxist economic theory, the 'law of value' fulfils a triple function. In the first place it *governs* (which does not mean that it determines here and now) the exchange relations between commodities; that is to say, it establishes the *axis* around which *long-term changes* in relative prices of commodities oscillate. (This includes under capitalism also the exchange relation between capital and labour, an extremely important point to which we shall return presently.) In the second place it determines the relative proportions of total social labour (and this implies, in the last analysis, total material resources of society) devoted to the output of different groups of commodities. In this way, the law of value distributes in the final analysis material resources over different branches of production (and of social activity in general) according to the division of 'effective demand' for different groups of commodities, it being always understood that this occurs within the framework of antagonistic class relations of production and distribution. In the third place it rules economic growth, by determining the average rate of profit and directing investment towards those firms and sectors of production where profit is above average, and away from those firms and sectors where profit is below average. Again, these movements of capital and investment correspond in the final analysis to conditions of 'economy' and 'waste' of social labour, that is to the workings of the law of value.

Marx's labour theory of value is a further development and perfection of the labour theory of value as it emanated from the 'classical' school of political economy, and especially of Ricardo's version. But the changes Marx brought into that theory were manifold. One especially was to be decisive: the use of the concept of *abstract social labour* as the foundation of his theory of value. It is for this reason that Marx cannot be considered as in any way an 'advanced neo-Ricardian'. 'Labour quantities as the essence of value' is something quite different from 'labour quantities as *numéraire*' – a common measuring rod of the value of all commodities. The distinction between concrete labour, which determines the use-value of commodities, and abstract labour, which determines their value, is a revolutionary step forward beyond Ricardo of which Marx was very proud; indeed he considered it his main achievement, together with the discovery of the *general* category of surplus-value, encompassing profit, rent and interest. It is based on an understanding of the peculiar structure of a society of commodity-producers, that is of the key problem of how to relate to each other the segments of the global labour potential of society which have taken the form of private labour. It represents, therefore, together with Marx's concept of necessary labour and surplus labour (necessary product and surplus product), the key nexus between economic theory and the science of social revolution, historical materialism.

The way in which the Marxist labour theory of value sharply excludes use-value from any direct determination of value and exchange-value has often been interpreted as a rejection by Marx of use-value beyond the boundary of economic analysis and theory altogether. This does not correspond at all to the rich dialectical complexity of *Capital*. When we deal with the problems of reproduction, in the introduction to Volume 2, we shall have occasion to dwell on the specific way in which the contradiction between use-value and exchange-value *has* to be bridged under capitalism, in order to make economic growth at all possible. Here, we only want to stress that, for Marx, the commodity was understood as encompassing *both* a unity and a contradiction between use-value and exchange-value: a good with no use-value for any potential buyer could not realize its exchange-value; and the specific *use-value* of two categories of commodities, means of production and labour-power, played a key role in his analysis of the capitalist mode of production.

As has already been stated, the law of value fundamentally expresses the fact that in a society based upon private property and private labour (in which economic decision-making is fragmented between thousands of independent firms and millions of independent 'economic agents') social labour cannot immediately be recognized as such. If Mr Jones has his workers produce 100,000 pairs of shoes a year he knows that people need shoes and buy them; he even knows, if he bothers to do his homework, that the annual number of shoes sold in the United Kingdom (and all those countries to which he intends to export his output) vastly outdistances the modest figure of 100,000 pairs. But he has no way of knowing whether the *specific* 100,000 pairs of shoes he owns will find specific customers willing and able to buy them. Only after selling his shoes and receiving their equivalent can he say (provided he has realized the average rate of profit on his invested capital): my workers have truly spent socially necessary labour in my factory. If part of the produced shoes remain unsold, or if they are sold at a loss or at a profit significantly less than the average, this means that part of the labour spent on their production has not been recognized by society as socially necessary labour, has in fact been wasted labour from the point of view of society as a whole.

But this 'recognition of' or 'refusal to recognize' a given quantity of labour by society occurs exclusively in function of meeting effective demand on the market, that is it is independent of the use-value or social usefulness of the specific physical qualities of a given commodity. Society recognizes quantities of labour spent in its production, making abstraction of these considerations. That is why Marx called these quantities, quantities of abstract socially necessary labour. If a pound of opium, a box of dum-dum bullets or a portrait of Hitler find customers on the market, the labour which has been spent on their output is socially necessary labour; its production has been value-production. If, on the contrary, an exquisite piece of china or a new pharmaceutical product for some reason does not find customers, its production has created no value, has been equivalent to a waste of social labour – even if, in some distant future, their creators will be celebrated as geniuses or benefactors of mankind. The labour theory of value has nothing to do with judgements on the usefulness of things from the point of view of human happiness or social progress. It has even less to do with establishing 'conditions for justice in exchange'. It simply recognizes the deeper meaning of the actual act of exchange and of the output of commodities under capitalism, and what governs the distribution of income between social classes which results from these acts, independently of any moral, aesthetic or political judgement. Indeed, if one were to look for such 'judgements', one would have to say that Marx, while understanding why the law of value has to operate as it does under commodity production, did not at all strive to 'defend' that law, but on the contrary to build a society in which its operations would be totally abolished.

One of the most common and innocuous objections made against Marx's labour theory of value runs along these lines: if prices are governed in the last analysis by value (socially necessary quantities of abstract labour), how can goods have prices if they are not products of labour, that is if they have no value? Marx himself in fact answered that objection long before drafting *Capital* Volume 1.[38] Products of nature ('free goods'), which have indeed no value since no social labour has been spent on their production, can get a price through private appropriation, through the social institution of private property. Land on which no human hand has ever worked to increase its fertility has no value. But it can get a price if it is surrounded by a fence upon which is put a placard 'Private property: Trespassing forbidden', and if people are ready to pay that price because they need that land as a source of livelihood. This price will in reality be the capitalization of the net income (land rent) accruing to its owner, income produced by those who will farm it and draw material resources (goods for self-consumption or commodities) from it through their toil.[39]

---

[38] See *A Contribution to the Critique of Political Economy*, p. 62.

[39] Again and again the objection has been raised against the Marxist labour theory of value that it 'assumes' labour to be the only scarce factor of

In reaction against all those who mistakenly claimed that Volume 1 of *Capital* was concerned with showing that commodities actually exchange under capitalism according to the quantities of abstract socially necessary labour they contain, some authors have contended that the labour theory of value is concerned only with a *qualitative* problem and not with a *quantitative* one, the 'socially necessary' labour content of commodities being unmeasurable. This bends the stick too far in the other direction. It is true that the quantitative measurement of the labour quantities in commodities is difficult. But the difficulty is not so much a conceptual one (one could, for example, start from macro-economic aggregates, the total sum of man-hours spent in the whole realm of material production – industry, agriculture and commodity transport – in a given country, its division between different branches of industry and key groups of commodities, their interrelationship through an input-output table, the labour spent for the average unit produced in 'autarchic' branches where no raw material has to be imported from foreign lands, and so climb up towards an estimate of total labour expenditure per branch and per commodity produced . . .) as one stemming from a lack of accurate information. It will be necessary to 'open the books' of all capitalist enterprises and to verify these figures on the basis of shop-floor evidence in order to approach a quantitative

---

production and supposes either that land and machines are abundant or that they can be excluded altogether from value analysis. This is obviously nonsense. Leontief makes the correct point that Marx was probably the first economist to give fixed capital a central importance in the process of production, as against, for example, Böhm-Bawerk (op. cit., p. 93). What Marx does assume is that machines cannot in and by themselves 'command' portions of the total available labour-power of society to be additionally expended or to move from one sector of production to another – a proposition which is rather self-evident, besides having been scientifically proved by Marx. Once one understands that, for Marx, value is in the last analysis assignment of portions of the socially available labour-power, total value newly produced being equal to total expenditure of living labour in a given period, one solves the riddle. Incidentally, one should also understand that Marx, advancing beyond classical economy, did not 'dissolve' the value of the annual product into wages and surplus-value (profits, rents and interests), but added to this the value of raw materials and machinery used up in the process of production. His only point was that this part of the annual product's value did not increase in the process of production but was only maintained, the only source of *new* value being living labour.

measurement of the labour content of commodities in capitalist countries.[40]

6. MARX'S KEY DISCOVERY: HIS THEORY OF SURPLUS-VALUE

The classical school of political economy, including Ricardo, saw profits as a residual net income, once wages had been paid. Indeed, so strict was their adherence to this concept that Ricardo believed that only increases or decreases in production costs in the wage-good industries could influence the rate of profit. Whatever happened to the luxury goods industry, or even to raw materials, would not affect the global rate of profit.

This view is incomplete and therefore incorrect, But it was at least an attempt to come to grips with the problem of income distribution between social classes as a function of what happens in the course of production. The exponents of post-Ricardian 'vulgar' economic theory, and especially the neo-classical marginalists, do not bother to ask the question 'why?', they are content just to answer the question 'how?'. They simply note that 'factors' (labour, capital, land) get different 'prices' on the market, and limit themselves to a study of how these prices fluctuate. To consider the *origins* of profit, interest and rent; to ask whether workers *must* abandon part of the product of their labour when they work for an alien entrepreneur; to examine the mechanisms through which this appropriation occurs as a result of an honest-to-god act of exchange, without any cheating or plotting: it was left to Marx to unravel these basic questions about the capitalist mode of production.

The origin of the income and consumption of the ruling classes in pre-capitalist societies is no matter of speculation. Anybody knows that, from an economic point of view, they were the results of appropriation of part of the fruits of the producers' labour by the ruling class. When the medieval serf worked half the week for his own livelihood on the land of his manse, and the other half of the week without remuneration on the estate of the noble or the church, one could argue that, from a 'moral' point of view, he was offering unpaid labour 'in exchange' for the 'service' of profane or divine protection. But nobody would confuse this 'exchange' with what goes on in the market place. It was in fact no economic exchange at all, in any sense of the word, no give-and-take of anything which can be 'priced', in even the most indirect way. The 'service of protection' is not 'bought' by the serf any more than a small Chicago businessman 'buys a service' from a gang of hoodlums. It is an extortion imposed upon him by the social set-up, whether he likes it or not. The origin of the social surplus product accruing to the pre-capitalist ruling class is, therefore, obviously unpaid labour (whether in the form of labour services, or of physical products of these labour services, or even of money-rent) expended by the producers.

---

[40] Friedrich Engels' insert in *Capital*, Vol. 3, pp. 74–6.

In the case of slavery, the context is as clear if not clearer, especially in those extreme examples where even the miserable pittance of the slave was not provided by the masters, but had to be provided by the slave himself on the seventh day of the week. Indeed, regarding these slave plantations, even the most sceptical critics of historical materialism will find it hard to doubt that the whole social product, the part which fed the slaves as well as the part which fed the masters, had but one origin: social labour expended by the slaves and by them alone.

When, however, we look at the capitalist mode of production, everything seems much more complicated and much more obscure, to say the least. No brutal force, personified by an overseer with a whip or some group of armed men, appears to force the worker to give up anything he has produced or owns himself. His relationship with the capitalist appears to be based upon an act of exchange which is identical to that of a small artisan or a farmer, owners of commodities they themselves have produced, who meet in the market place. The worker appears to sell his 'labour' in exchange for a wage. The capitalist 'combines' that labour with machines, raw material and the labour of other men to produce finished products. As the capitalist owns these machines and raw materials, as well as the money to pay the wages, is it not 'natural' that he should also own the finished products which result from the 'combination of these factors'?

This is what *appears* to occur under capitalism. However, probing below the surface, Marx comes up with a series of striking observations which can only be denied if one deliberately refuses to examine the unique social conditions which create the very peculiar and exceptional 'exchange' between labour and capital. In the first place, there is an institutional inequality of conditions between capitalists and workers. The capitalist is not *forced* to buy labour-power on a continuous basis. He does it only if it is profitable to him. If not, he prefers to wait, to lay off workers, or even to close his plant down till better times. The worker, on the other hand (the word is used here in the social meaning made clear precisely by this sentence, and not necessarily in the stricter sense of manual labourer), is *under economic compulsion* to sell his labour-power. As he has no access to the means of production, including land, as he has no access to any large-scale free stock of food, and as he has no reserves of money which enable him to survive for any length of time while doing nothing, he *must* sell his labour-power to the capitalist on a continuous basis and at the current rate. Without such institutionalized compulsion, a fully developed capitalist society would be impossible. Indeed, once such compulsion is absent (for example where large tracts of free land subsist), capitalism will remain dwarfed until, by hook or by crook, the bourgeois class suppresses access to that free land. The last chapter of *Capital* Volume 1, on colonization, develops this point to great effect. The history of Africa, especially of South Africa, but also of the Portuguese, Belgian, French and British colonies, strikingly confirms this analysis.[41] If people are living under conditions where there is no *economic* compulsion to sell their labour-power, then repressive *juridical* and *political* compulsion has to deliver the necessary manpower to the entrepreneurs; otherwise capitalism could not survive under these circumstances.

The function of trade unions, be it said in passing, is immediately clarified in the light of this analysis. Workers who combine to set up a reserve fund can be freed at least for some weeks from the compulsion to sell their labour-power on a continuous basis at the given market rate. Capitalism does not like that at all. It is contrary to 'nature'; if not to human nature, then at least to the deeper nature of bourgeois society. That is why, under robust nascent capitalism, trade unions were simply banned. That is also why, under senile capitalism, we are gradually returning to a situation in which workers are denied the right to strike – the right to abstain from selling their labour-power at the offered price whenever they like. In this instance, Marx's insight is clearly confirmed by the highest authorities of the bourgeois state: under capitalism, labour is fundamentally *forced* labour. Whenever possible, capitalists prefer hypocritically to cloak the compulsion under a smokescreen of 'equal and just exchange' on the 'labour market'. When hypocrisy is no longer possible, they return to what they began with: naked coercion.

---

[41] We refer here to the large-scale appropriation of land by white settlers and colonial companies, the herding together of Africans into 'reserves', the imposition of money taxes in essentially non-monetary economies, forcing the Africans to sell their labour-power in order to get the necessary money to pay taxes, the imposition of large-scale money fines, or even direct forced labour penalties for innumerable transgressions of laws specially designed to furnish the settlers with labour-power, etc., etc.

Marx, of course, was perfectly well aware of the fact that, in order to organize production in modern factories, it was not enough to combine the social labour-power of manual and intellectual workers. It was necessary to provide for land, buildings, energy, infrastructural elements like roads and water, machinery, a given fabric of organized society, means of communication, etc. But it is obviously absurd to presume that, because factory production is impossible without these conditions of production, roads and canals therefore 'produce value'. It is no more logical to assume that machines 'produce' any value, in and by themselves. Of all these 'factors' it can be said only that their given value has to be maintained and reproduced, through incorporation of part of it in the current output of living labour, during the production process.

We come nearer to the truth when we note that *property titles* (private appropriation rights) to land and machinery lead to a situation where these 'factors' will not be incorporated into the process of production without their proprietors receiving an expected 'return' over and above the compensation for the wear and tear of the 'factors'. This is obviously true. But it does not follow at all that such 'returns' are then 'produced' by the property titles. Nor does it imply that owners of such property titles meet the owners of labour-power on an equal footing. Only if we were in a 'capitalistic slave society', where owners of slaves hired out labour-power to owners of factories renting land from landed proprietors, could one say that institutional equality existed between all owners – though, of course, not between owners and slaves! Obviously, in that case, the slave owners would hire out their slaves only if they received a 'net return' *over and above the upkeep of the slaves.*

In the second place, the social situation in which a small part of society has monopolized property and access to the means of production, to the exclusion of all or nearly all direct producers, is in no way a product of 'natural inequality of talents and inclinations' among human beings. Indeed, it did not exist for tens of thousands of years of social life on the part of *homo sapiens*. Even in the relatively recent past, say 150 years ago, nine-tenths of the producers on this planet – who were in their overwhelming majority agricultural producers – did have direct access, in one way or another, to their means of production and livelihood. The separation of the producer from his means of production was a long and bloody historical process, analysed in detail by Marx in Part Eight of *Capital* Volume 1, 'So-Called Primitive Accumulation'.

In the third place, the worker does not sell the capitalist his labour, but his *labour-power*, his capacity to work for a given period of *time*. This labour-power becomes a commodity under capitalism.[42] As such it has a specific value (exchange-value), as any other commodity does: the quantity of social labour necessary to reproduce it – that is to say the value of the consumer goods necessary to keep the worker and his children in condition to continue to work at a given level of intensity of effort. But it has a

---

42. Obviously Marx did not 'transform' men into 'commodities', as so many of his 'ethical' opponents accuse him of doing. He noted that *capitalism* had operated such a transformation and therefore condemned capitalism. Popper significantly contends that 'the value theory [of Marx] . . . considers human labour as fundamentally different from all other processes in nature, for example from the labour of animals. This shows clearly that the theory is based ultimately upon a moral theory, the doctrine that human suffering and a human lifetime spent is a thing [!] fundamentally different from all natural processes . . . I do not deny that this theory is right in the moral sense . . . But I also think that an economic analysis should not be based upon a moral or metaphysical or religious doctrine of which the holder is unconscious' (*The Open Society*, Vol. 2, p. 329). In the first place, Marx was not at all unconscious of the differences between human labour and the endeavours of animals such as ants; he comments on it in the first chapter of *Capital* Vol. 1. In the second place, there is nothing metaphysical about the fact that, when men engage in mutual social relations in order to produce their livelihood, they will certainly consider human labour, as the basis of this social organization, quite differently from natural processes, fertility of the soil or of cattle, etc. There is nothing metaphysical about the distinction, *from man's point of view*, between chemical processes in trees and the necessary arrangements to divide the total labour time available to the community between different types of human activity. Two thousand years ago, defenders of the institution of slavery used to equate slaves with 'speaking instruments', or 'speaking beasts of toil'. We know very well that Popper does not condone slavery. Would he then say that this condemnation of slavery is purely 'metaphysical', or would he admit that it is based upon a scientific, anthropological distinction between man and animals?

special quality, a special 'use-value' for the capitalist. When the capitalist 'consumes' labour-power in the process of production, the *worker produces value.* His labour has the double capacity to *conserve value* – that is, to transfer into the finished product the value of the raw material and of a fraction of the machinery used up in this process of production – and to *create new value*, by spending itself. The whole mystery of the origin of profits and rents is over once one understands that, in the process of production, the workers can (and must – otherwise the capitalist would not hire them) produce value over and above the value of their own labour-power, over and above the equivalent of the wages which they receive. We are back where we started in pre-capitalist societies, and we have been able to eliminate the cobweb of apparent 'exchange equality': like feudal rent or the slave-owner's livelihood, capitalist profits, interests and rents originate from the *difference between what the workers produce and what they receive for their upkeep.* Under capitalism this difference appears in the form of value, and not of physical output. This fact prevents the process from being immediately transparent. But it does not make it fundamentally different from the 'exchange' taking place between feudal lord and serf.

It is therefore incorrect to state, as does Blaug, following other academic critics of Marx, that Marx's theory of surplus-value is a theory of 'unearned increment'.[43] It is an *appropriation* or *deduction theory* of the capitalists' income, as was the classical labour theory of value. Capitalists appropriate value which the workers have already produced, prior to the process of circulation of commodities and of distribution of income. No value can be distributed – from a macro-economic point of view, in other words viewing bourgeois society as a whole – which has not been previously produced.

Marx himself considered the discovery of the concept of surplus-value, representing the sum total of profits, interests and rents of all parts of the bourgeois class, as his main theoretical discovery.[44]

---

[43] Mark Blaug, 'Technical Change and Marxian Economics', *Kyklos* Vol. 3, 1960, quoted in Horowitz, op. cit., p. 227.

[44] 'Das Beste an meinem Buch ist 1. (darauf beruht *alles* Verständnis der facts) der gleich im *Ersten* Kapitel hervorgehobne *Doppelcharakter der Arbeit*, je nachdem sie sich in Gebrauchswert oder Tauschwert ausdrückt; 2. die Behandlung des *Mehrwerts unabhängig von seinen besondren* Formen als Profit, Zins, Grundrente etc. Namentlich in 2. Band wird dies sich zeigen' (Marx, letter to Engels of 24 August 1868, *MEW* 31, p. 326).

It ties together the historical science of society and the science of the capitalist economy, explaining both the origins and content of the class struggle and the dynamic of capitalist society.[45]

For once we understand that surplus-value is *produced* by workers, that surplus-value is nothing but the age-old social surplus product *in money form*, in the form of value, we understand the historical leap which occurred when that social surplus product no longer appeared essentially in the form of luxury goods (of which consumption is necessarily limited, even under conditions of such extreme extravagance as during the Roman Empire or in the eighteenth-century French court) but in the form of money. More money means not only additional purchasing power for such luxury goods, but additional purchasing power for more machines, more raw materials, more labour-power. Here too Marx discovered an economic compulsion. Private property, the fragmentation of social labour among various firms, that is, the very nature of generalized commodity production – capitalism – implies a compulsion to compete for shares of the market. The need to accumulate capital, the need to increase the extraction of surplus-value, the unquenchable thirst for surplus-value which characterizes capitalism, it is all here: the accumulation of capital = the transformation of surplus-value into additional capital.

Again, as for value, we should note what this is all about: command over fractions of the total disposable quantity of social labour. It is sufficient to recall this basic fact to understand how misplaced are criticisms of the theory of surplus-value which speak about the 'productivity of capital', capital being understood as machines.[46] Machines can never, in and by themselves, hire any fraction of the disposable social labour force, except in science fiction. In the more prosaic world in which we live, *men* owning machines can, for that reason, hire and fire other men. How the product of the labour of these men is then divided, and why, is what Marx seeks to explain.

---

[45] Popper (*The Open Society*, Vol. 2, p. 160) contends that Marx did not discover the general category of surplus-value at all, but inherited it from Ricardo. He quotes Engels' introduction to Vol. 2 of *Capital* in that respect. Engels says nothing of the kind. He states, as any student of economic doctrines knows, that a long series of economists, from Adam Smith and the physiocrats to Ricardo and the post-Ricardian anti-capitalists of the eighteen twenties and thirties in Britain, considered profits and rents to be subtractions from the products of 'productive labour'. But only Marx succeeded in showing *what kind of labour* produces surplus-value and what the real content of the process of surplus-value production is, irrespective of its specific forms, and in *explaining* this process.

[46] Samuelson, following Böhm-Bawerk, derives this 'productivity of capital' from the fact that 'you can get more future consumption product by using indirect or roundabout methods' (*Economics, an Introductory Analysis*, New York, 4th edition, pp. 576–7). In the explanation which follows, the

Of course, Marx did not 'deny' that machinery could increase the social productivity of labour. On the contrary, if one reads Chapter 15 of *Capital* Volume 1, one will see immediately that he was more aware of that potential of technology than any economist among his contemporaries. But the question which most of his critics and other exponents of 'vulgar' economics overlook is very simple, namely, why should the results of the increased productivity of labour be appropriated by the capitalist? Why should the combined productivity of many men working together – the famous 'collective labour potential of the factory' to which a key analysis is devoted in the original Part Seven ('Chapter Six') omitted from the published version of *Capital* Volume 1 (see appendix to this volume, pp. 943–1084) – the combined productivity of scientists and technologists, workers by hand and brain, inventors of machinery and flexers of muscle, increase the profit of the owners of machinery? Surely not because that machinery has some mysterious quality of 'creating' value, that is of 'creating' quantities of socially necessary labour?[47] Surely rather because the owners are in a position to appropriate the products of that combination. So we are back to Marx's theory of surplus-value.

An interesting, if somewhat astounding, innovation in apologetics for capitalist profits has recently occurred in the form of the theory of the firm developed by Alchian and Demsetz.[48] Owners of different 'co-operating inputs' are supposed to have a natural tendency to shirk, because they give some preference to 'non-

---

'increment', however, originates from the fact that 'current consumption' is 'sacrificed' for the production of 'intermediate goods'. But it is *people* who forgo consumption (we leave aside *which* people really are forced into abstinence). People *produce* intermediate goods. People increase the productivity of their *labour*. How all these *human* operations suddenly lead to value oozing out of 'intermediate goods' (called 'productivity of capital') is a mystifying secret which Samuelson does not solve.

[47] The only quality machines have 'in and of themselves' is to increase the productivity of labour and thereby to *decrease* the value of commodities – not to 'create' value.

[48] A. Alchian and H. Demsetz, 'Production, Information Costs and Economic Organisation', *American Economic Review*, 1972.

pecuniary goods' (!) such as leisure, attractive working conditions and time to converse with fellow workers. It follows, according to Alchian and Demsetz, that if shirking is to be checked someone must have both the right to monitor the performance of team members and the disinclination to shirk himself. To this end he must have the right to receive the *residue* after all other inputs have been paid contractual amounts, the right to terminate membership of the team and the right to sell these rights. After having received with great joy the good tidings that he has now been promoted to the status of member of a 'co-operative team', on an equal footing with the capitalist, the average worker cannot fail to wonder for what mysterious reason the 'someone' who gets all these 'economically necessary rights' is *always* the owner of the 'input – means of production' and *never* the owner of the 'input – labour-power'. Would it be because the capitalist is free from the human vice of shirking, or has no inclination to leisure or attractive working conditions? Or is it perhaps because Messrs Apologists for Capitalism are trying to argue away the fact of surplus-value appropriation through monopoly ownership of the means of production?

7. MARX'S THEORY OF CAPITAL

Capital is thus, from the Marxist point of view, a *social relation between men* which appears as a relation between things or between men and things. Flowing logically from Marx's labour theory of value and theory of surplus-value, this is another of the key discoveries which opposes his economic theory radically to all forms of academic 'economics'.

Marx energetically rejects the idea, as expounded by 'vulgar' and neo-classical economists, that 'capital' is just 'any stock of wealth' or 'any means to increase labour productivity'.[49] A chimpanzee using a stick to get at bananas is no more the first capitalist than a tribal community learning to accrue its wealth through animal husbandry or land irrigation is 'accumulating capital'. Capital presupposes that goods are not being produced for direct consumption by the producing communities, but are sold as commodities; that the total labour potential of society has become fragmented into private labours conducted independently of each other; that commodities therefore have value; that this value is realized through exchange with a special commodity called money; that it can therefore start an independent process of circulation, being property of a given class of society whose members operate as owners of value looking for increments of value. If, as Adam Smith explained to successive generations of students of economic phenomena, productive (technical) *division of labour* is a source of increased labour productivity – to a large extent independently from the specific social form of organization of the economy – then capital is not a product of that division of labour, but of a *social division of labour*, in which owners of accumulated value face non-owners.

---

[49] Joseph Schumpeter, *History of Economic Analysis*, New York, 1954, pp. 558–9.

Joseph Schumpeter reproached Marx with having elaborated a theory of capital which was unable to explain the origins of capital.[50] Nothing is further from the truth. Marx the dialectician perfectly understood the difference between, on the one hand, the production and reproduction of capital on the basis of the capitalist mode of production and, on the other, the origins and development of capital in pre-capitalist modes of production. Indeed, one of the essential objections to the imprecise and unscientific handling of categories by 'vulgar' economists was their undifferentiated use of the terms 'capital' and 'capitalism' as more or less synonymous. *Capitalism* is the capitalist mode of production, the seizure of the means of production by capital, which has become predominant in the sphere of production. *Capital* is value (initially in the form of money) becoming an independent operator in the pores of a non-capitalist mode of production. Capital appears initially as usury and merchant (long-distance trade) capital. After a long historical process, and only under specific social conditions, does capital victoriously penetrate the sphere of production in the form of manufacturing capital. (This occurred in the late fifteenth and sixteenth centuries in Western Europe; in the eighteenth century in Japan. In China, *isolated elements* of manufacturing capital had probably already appeared more than a thousand years earlier.)

In simple commodity production, capital does not *produce* surplus-value. It simply transforms into surplus-value parts of current output and revenue which originate independently from capital. It can appropriate part of the social surplus product normally passing into the hands of pre-capitalist ruling classes (for instance the appropriation, through usury, of part of the feudal land rent). It can appropriate part of the product which normally serves as a consumption fund for the producers themselves. The basic characteristic of these operations of capital under pre-capitalist relations of production is that it will barely increase the global wealth of society; it will neither significantly develop productive forces nor stimulate economic growth. It can only have a disintegrating effect on the given pre-capitalist social order, precipitating the ruin of several social classes. However, by accelerating the transformation of goods produced and consumed as use-values only into commodities, that is by accelerating the spread of money economy, it can historically prepare the ground for an eventual appearance of the capitalist mode of production.

---

[50] Schumpeter, *Capitalism, Socialism and Democracy*, pp. 15–18.

Capital operating in pre-capitalist modes of production refers essentially to a theory of money circulation and appropriation. This is why in Volume 1 of *Capital* Marx first introduces capital in Part Two, *after* having explained the nature of money. Indeed, Part Two is entitled 'The Transformation of Money into Capital'. Here again, the logical analysis corresponds to the historical process, to which Marx continually refers, albeit for the most part in footnotes. On the other hand, capital operating in the capitalist mode of production, the real object of study of *Capital*, refers obviously to a theory of production and appropriation of value and surplus-value. Marx explains in Volume 1, Chapter 24, how the law of appropriation of commodities is transformed when we pass from a society of petty commodity producers to a capitalist society. In the first case, the direct producers are owners of the products of their labour; in the second, the owners of capital become the owners of the products of the labour of the direct producers. Apologists for capitalism try to justify this fact by the argument that, after all, capitalists 'place at the disposal' of the workers the tools with which production occurs.[51] But again history allows us to pierce through the hypocrisy of the argument. For capitalism was not born – in the days of manufacturing – with the capitalist 'putting at the disposal of the producers' any new machinery. It was born with the capitalists *expropriating* the tools owned by the producers themselves and assembling these very tools under a common roof.[52]

---

[51] For example, MacCord Wright, *Capitalism*, New York, 1951, p. 135. In the 'Results of the Immediate Process of Production', Marx shows how mystifyingly capitalism represents increases in the *social productivity of labour*, through *social* developments like scientific progress, co-operation of many workers, etc. as results of the 'productivity of capital'.

Capital, under the capitalist mode of production, is therefore value constantly increased by surplus-value, which is produced by productive labour and appropriated by capitalists through the appropriation of the commodities produced by the workers in factories owned by capitalists. The way in which this analysis of capital and capitalism hinges on the institution of private property has often been misunderstood or (and) misrepresented, both by critics and by disciples of Marx. It therefore merits some comment.

Historically and logically, capitalism is tied to the private ownership of the means of production, which allows private appropriation of produced commodities, thus private appropriation of surplus-value, and thus private accumulation of capital. It is surely not accidental that the 'rights of private property' are thus at the bottom of the whole constitutional and juridical superstructure which centuries of law-making have erected upon the basis of commodity production.

But what we confront when we examine the social relations which lie behind these juridical forms is, of course, something which is not simply formal private property; otherwise the analysis would be reduced to simple tautology. When Marx states that commodity production is only possible because social labour has been fragmented into *private labours conducted independently from each other*,[53] he refers to a *socio-economic* and *not* a juridical reality; the latter is only a reflection – and sometimes a very imperfect one! – of the former. What capitalism is about, then, is a specific relation between wage-labour and capital, a social organization in which social labour is fragmented into firms independent of each other, which take independent decisions about investment, prices and forms of financing growth, which compete with each other for shares of markets and profits (of the total surplus-value produced by productive labour in its totality), and which *therefore* buy and exploit wage-labour under specific economic conditions, compulsions and constraints. It is not simply a general relationship between 'producers' and 'accumulators', or 'producers' and 'administrators', for such a relationship is in the last analysis characteristic of all class societies and not specific to capitalism at all.

---

[52] On this aspect of the development of home industries and of the first manufactures in the fifteenth and sixteenth centuries, see, among other sources, N. W. Posthumus, *De Geschiedenis van de Leidsche Lakenindustrie*, 's-Gravenhage, 1908.

[53] See below, p. 165. In a note added by Engels in the fourth German edition of *Capital* Vol. 1 (see p. 138 below), he makes the point that in English there are two different words to express the two different aspects of labour: use-value-producing labour is called *work*, exchange-value-producing labour, which is only quantitatively measured, is called labour.

The *content* of the *economic* institution of private capital is therefore the *independent firm* (whether a small manufacturer or a giant multi-national corporation). Whether the *juridical form* strictly conforms to that content or not is irrelevant, and often poses complex legal problems. Are stockholders only owners of income titles, or are they owners of fractions of the firm's 'assets' or 'property'? The bankruptcy laws – which differ in different capitalist countries – can go into the most sophisticated nuances imaginable on this subject. But the vital economic decisions (key investment decisions, for example) are taken by all those firms which are really independent and not subordinate companies. The basic fact of life of the capitalist economy is the fact that these vital decisions are not taken by society as a whole or by the 'associated producers'.

Again, the content of this *economic* institution of private property (fragmented social labour) should not be confused with the question of the precise *agents* who take the independent firms' decisions. Whether those who take the decisions are individual owners, or representatives of stockholders, or so-called managers, does not in the least change the fact that they are working under the same previously analysed economic compulsion. Some economists today, such as Galbraith and even some Marxists, contend that the contemporary giant corporation has largely freed itself from these constraints.[54] This is an illusion, born of an extrapolation from conditions prevailing during a rather lengthy boom. In fact, the idea that any giant corporation, whatever its dimensions or power, could emancipate itself definitively from the compulsion of (monopolistic) competition, that is, could have a guaranteed specific demand for its products, independently of the trade cycle and from technological innovation, could make sense only if it were insulated both from economic fluctuations and from economic uncertainty, that is if the very nature of its output as commodity production was denied. Experience does not confirm such a contention.

---

[54] John Kenneth Galbraith, *The New Industrial State*, New York, 1967, Chapter 18.

The basic distinction which Galbraith, following Baumol, Kaysen and others, introduces between compulsion to profit maximization (true for yesterday's firms) and compulsion to growth maximization (true for today's corporations)[55] becomes devoid of practical long-term significance once we understand that growth remains essentially a function of profit, that capital accumulation can result in the last analysis only from surplus-value production and realization. The only kernel of truth which remains, then, is the difference between short-term and long-term profit maximization, which is indeed one of the basic differences between competitive capitalism and monopoly capitalism.

The debate on the nature of capital has received a new and significant impetus with the 'internal' critique of the theory of the marginal productivity of capital by Piero Sraffa and the Cambridge school. The latter have demonstrated convincingly that the measurement of capital inputs in the neo-classical 'production function' is based upon circular reasoning.[56] For if the effect of marginal increases or decreases of capital inputs upon output has to be *measured*, this can only be done in money terms, given the heterogeneous nature of so-called 'capital goods'. 'But this process of pricing or valuation of capital inputs presupposes a rate of return on the plant and equipment in question, of which the latter value is the capitalization'; that is 'one has to *assume* a rate of interest in order to demonstrate how this equilibrium rate of return is determined'.[57] The way out, obviously, is to look for a common substance in all the 'capital goods' independent of money, that is to return to socially necessary labour as the measurable substance of the value of all commodities.

57. Maurice Dobb, 'The Sraffa System and the Critique of the Neo-Classical Theory of Distribution', reprinted in E. K. Hunt and Jesse G. Swartz (ed.), *A Critique of Economic Theory*, Harmondsworth, 1972, p. 207. One should note, however, that, to use the Schumpeterian jargon, Dobb thus only justifies the use of labour as a *numéraire* (a unit of account), in a typically neo-Ricardian way, and not at all on the basis of the Marxist labour theory of value.

8. MARX'S THEORY OF ACCUMULATION OF CAPITAL

Capital is thus, by definition, value looking for accretion, for surplus-value. But if capital produces surplus-value, surplus-value also produces additional capital. Under capitalism, economic growth therefore appears in the form of accumulation of capital. The basic drive of the capitalist mode of production is the drive to accumulate capital. This is not so because of some mysterious and tautological 'accumulative passion' or inclination on the part of capitalists. It is essentially explained by competition, that is by the phenomenon of 'various capitals'. Without competition, Marx states categorically, the 'driving fire' of growth would become extinguished.[58] Totally monopolized capital ('a single world trust') would essentially be stagnating capital.

But competition is combined with the trend to replace labour by machinery as a driving force for capital accumulation and economic growth under capitalism. If the extension of output maintained the given relationship between inputs of living labour and inputs of dead labour (machinery and raw materials), it would rapidly reach both a physical limit (the total available manpower) and hence a profit limit. Under conditions of permanent full employment, wages would tend to increase and erode profits to the point where capital accumulation and economic growth would gradually disappear.

Under capitalism, however, economic growth is not 'neutral' with respect to the relationship between living and dead labour inputs (between variable and constant capital). It is heavily loaded in favour of an expansion of labour-saving devices. Indeed, a permanent tendency to increase the social productivity of labour is the main civilizing by-product of capital accumulation, the main objective service which capitalism has rendered mankind. Capital accumulation takes on the primary form of an increase in the value of plant and equipment, as well as of the stock of raw materials available in industrialized capitalist countries. On a long-term basis, this accumulation is as impressive as Marx could have imagined. The value of all accumulated private non-farm producer durables multiplied more than tenfold in constant dollars between 1900 and 1965 in the U.S.A., and this estimate is certainly undervalued as it is based upon official records biased for reasons of tax evasion.

---

[58] Karl Marx, *Capital*, Vol. 3, p. 254.

Capital accumulation is, of course, distinct from the behaviour of pre-capitalist ruling classes. If all surplus-value were to be consumed in the form of luxury goods, no capital accumulation would take place at all. Capital would then be maintained at the level it had already reached. This special 'limiting' case was indeed presented by Marx under the name of 'simple reproduction', for purely analytical reasons. It does not, of course, correspond to any 'real' stage or situation of a normally functioning capitalist mode of production.[59] As we pointed out, what characterizes capitalism is precisely the compulsion to accumulate, that is 'enlarged reproduction'.

Enlarged reproduction presupposes that not all surplus-value produced by productive labour, and appropriated by the capitalist class, is unproductively consumed. Part of it is transformed into luxury goods and disappears from the process of reproduction. Part of it is transformed into additional capital by being used to buy additional plant and equipment, additional raw materials and additional labour-power. This, then, is the process of accumulation of capital: the transformation of surplus-value into additional capital, which can produce new increments of surplus-value, leading to new increments of capital. The movement develops in the form of a spiral, as Simonde de Sismondi, one of the early 'romantic' critics of capitalism, whom Marx quotes approvingly on this question, already understood.

The fact that capital accumulation is possible only because part of the surplus-value appropriated by the capitalist class is not socially squandered in luxury goods constitutes the starting point for the so-called 'abstinence' theory (more accurately, justification) of profits and capitalist exploitation.[60] Historically, there is not an atom of evidence for the assumption that capital somehow grew out of the 'frugal habits' of some members of the community, as opposed to the 'improvidence' of others, each of them having equal access to resources that were initially comparable. On the contrary, all historical evidence confirms that the sudden appearance of large amounts of 'capital' (in the form of a stock of precious metals and other treasure) in a society previously confined almost exclusively to natural economy (to the output of goods possessing only use-value) was the result not of 'frugality' and 'thrift' but of large-scale piracy, robbery, violence, theft, enslavement of men and trade in slaves. The history of the origins of West European usury and merchant capital between the tenth and the thirteenth centuries, from the piracy in the Mediterranean through the plundering of Byzantium by the Fourth Crusade to the regular plundering razzias into the Slav territories of Central and Eastern Europe, is very eloquent in this respect.

---

[59] One could say that it corresponds to a border case of stagnation in a given phase of the trade cycle.

[60] Even Schumpeter still largely defended this 'abstinence' theory of profit, although giving it a less vulgar character than in the case of Senior. 'The capitalist ... exchanges a fund against a flow. The "abstinence" for which ... he is being paid enters into the accumulation of the fund. There is no additional payment for refraining from consuming it even in cases in which this would be physically possible' (*History of Economic Analysis*, p. 661). See also *Capitalism, Socialism and Democracy*, p. 16.

What is unconfirmed by history is even more absurd in the light of contemporary economic analysis. Nobody could seriously argue that Messrs Rockefeller, Morgan and Mellon have to be compensated for their virtue in not squandering tens of billions of dollars on additional yachts, mansions and private jets – the vulgar version of the abstinence theory. But its more sophisticated version, namely the idea that the profits of the owners of capital are just the way in which their 'fund' is transformed into the 'flow' of long-term capital investment, provides a nice piece of circular reasoning. For whence does the 'fund' originate, if not precisely from the 'flow', that is to say what else is capital if not accumulated profits? To deny that profits originate in the process of production flies in the face of all scientific as well as practical observation of what goes on in a capitalist economy. Once we understand this, there is no room left for any abstinence theory of profit – only for a subtraction one.

The process of capital accumulation is viewed by Marx in *Capital* at two different and successive levels of abstraction. In Volume 1, in the framework of 'Capital in general', he examines it essentially in the light of what occurs in and flows from the exchange between wage-labour and capital. In Volume 3, he examines capital accumulation (economic growth under capitalism) in the light of what occurs in the sphere of 'many capitals', that is of capitalist competition. I shall therefore leave to the introduction to Volume 3 an examination of the main criticisms made of Marx by those who question the validity of the laws of motion of capital accumulation set out in that volume. Here, I shall limit myself to examining the basic effects of capital accumulation on wage-labour.

Unlike many of his contemporaries, including some of the sternest non-Marxist critics of capitalism, Marx did not consider that capital accumulation had a simple and unequivocally detrimental effect upon the situation of wage-labour. Marx had studied the movement of real wages during the trade cycle, and the fact that wages were at their highest level when capital accumulation was progressing at the quickest pace by no means escaped him.[61] But, once again, he tried to go beyond such evident facts to study the *fundamental modifications in value terms* which capital accumulation would exercise upon labour.

It thus became his contention that the very way in which capital accumulation proceeds, the very motive force of capitalist progress – the development of fixed capital, of machinery – contains a powerful dynamic to reduce the *value* of labour-power. For as this value is the equivalent of the value of a *given* quantity of consumer goods, supposed to be necessary to restore the capacity of a worker to produce at a given level of intensity, a decrease in the value of these consumer goods resulting from an increase in the productivity of labour in the consumer goods industry leads to a decrease in the value of labour-power, all other things remaining equal.

This argument implies neither any tendency to a decrease in real wages (on the contrary, it is based upon the assumption of *stable* real wages in the short and medium term), nor any trend towards 'growing absolute misery' of the working class. We shall deal with this theory falsely attributed to Marx in the next section of this introduction. But it does imply that the favourable results of the increase in productivity of labour end by falling, to a large extent, into the hands of the capitalist class, by transforming themselves into supplementary 'relative surplus-value', provided that the long-term trend of the industrial reserve army of labour is either stable or increasing.

On a world scale this has certainly been true for as long as capitalism has existed. As Marx predicted, capitalism spread not only by creating new jobs but also by creating new unemployed (by destroying employment of previous wage earners, and especially of previously self-employed small farmers and handicraftsmen). But to calculate a 'world average value of labour-power' is of course a meaningless abstraction. Indeed, ever since industrial capitalism in the West started to swamp the rest of the world with its cheap, mass-produced commodities, and at the latest since the eighteen-seventies, a *divergent* trend has appeared in the world economy: a long-term decline of the reserve army of labour in Western Europe (as a result of exports of both emigrants and commodities) and a rise in the reserve army of labour in the underdeveloped countries. (This latter process included, of course, the transformation of masses of pre-capitalist farmers, cattle-raisers and artisans into uprooted 'marginalized' vagrants, migrant seasonal labourers, and forced labourers, following a pattern similar to what had happened a few centuries earlier in Western Europe.)

---

[61] Karl Marx, 'Wages, Price and Profit', in *Selected Works* in one volume, London, 1970, pp. 220–21.

The dynamics of 'capital accumulation on a world scale' have therefore to be seen as those of an organic whole, and not as the simple sum of capital accumulation processes in distinct countries. The operation of the world market as a gigantic syphon to transfer value from the south to the north of our planet (from the countries with lower to the countries with higher productivity of labour) lies at the very root of the imperialist system. While the debate on the theoretical explanation of this phenomenon is still in its initial stages,[62] it is important to note that the phenomenon itself is based upon uneven movements (uneven mobility) of capital and labour, and introduces all those dimensions into the analysis of capitalism which Marx reserved for the never-written Volumes 4, 5 and 6 in the original plan of *Capital.*

The accumulation of capital is the accumulation of wealth in the form of commodities, of value. Value production becomes a goal in itself. Work is degraded to the level of a means by which to receive money incomes. One of the most striking and most 'modern' parts of *Capital* is that which examines the inhuman consequences of capital accumulation for the workers and for work itself. Marx himself added to the second German edition of Volume 1 the note that, under capitalism, labour-power not only becomes a commodity for the capitalist but also receives this form *for the worker himself*, implying that this degradation of work is both objectively and subjectively the fate of the industrial proletariat. It took 'official' political economy a long time, indeed until after the growing revolt of the workers against assembly line speed-ups, to discover what Marx had anticipated from a thorough understanding of the fundamental mechanisms which govern the capitalist mode of production.

---

[62] See, among other writings: Samir Amin, *L'Accumulation à l'échelle mondiale*, Paris, 1970; Arghiri Emmanuel, *Unequal Exchange* (including a discussion with Charles Bettelheim), London, 1972; Christian Palloix, *L'Économie mondiale capitaliste*, Paris, 1971; and the discussion of these books by Ernest Mandel in *Late Capitalism*, London, 1975. Interestingly enough, W. Arthur Lewis, in his 'Development with Unlimited Supplies of Labour' (Manchester School of Economic and Social Studies, Vol. XXII, May 1954), tries to show that stepped-up capital accumulation implies a large industrial reserve army; but he limits this case exclusively to initial industrialization and does not admit Marx's assumption of permanent reconstitution of this reserve army through the mechanization process.

Because capital accumulation presupposes production for profit, because it has profit maximization as its very *rationale*, exact and minute cost calculations entail constant reorganizations of the production process with the single purpose of reducing costs. From the point of view of the single capitalist firm, a worker cannot be seen as a human being endowed with elementary rights, dignity, and needs to develop his personality. He is a 'cost element' and this 'cost' must be constantly and exclusively measured in money terms, in order to be reduced to the utmost. Even when 'human relations' and 'psychological considerations' are introduced into labour organization, they are all centred in the last analysis upon 'economies of cost' (of those 'overhead costs' called excessive labour turnover, too many work interruptions, absenteeism, strikes, etc.).[63]

Capitalist economy is thus a gigantic enterprise of dehumanization, of transformation of human beings from goals in themselves into instruments and means for money-making and capital accumulation. It is not the machine, nor any technological compulsion, which inevitably transforms workers and men and women in general into appendices and slaves of monstrous equipment. It is the capitalist principle of profit maximization by individual firms which unleashes this terrifying trend. Other types of technology and other types of machine are perfectly conceivable – provided that the guiding principle of investment is no longer 'cost-saving' by individual competing firms, but the optimum development of all human beings.

[63] The most extreme case is that of 'globalization of costs' in cost-benefit analysis, in which human illness and death are likewise computed in the form of money costs.

9. MARX'S THEORY OF WAGES

Strangely enough, the idea of an ever-increasing decline in the standard of living of the working class, which has often been falsely attributed to Marx, originated with those economists against whom he maintained a constant barrage of polemics after perfecting his own economic theories. It originated with Malthus and, via Ricardo, reached several socialists of Marx's generation, such as Ferdinand Lassalle. Whether under the guise of a 'stable wage fund' or under the guise of an 'iron law of wages', it is essentially a *population growth theory of wages*. Whenever wages rise sufficiently above the physiological minimum, labourers are supposed to have more children, who then in turn create large-scale unemployment and depress wages back to the minimum.

The logical shortcomings of this theory are glaring. It examines only what happens on the supply side of labour-power; it does not examine at all what happens on the demand side. It presupposes that the potential working population is a linear function of population increase, and that the demographic movement is in turn a linear function of real income. All the intermediate links – like the effects of increases of income not only upon the child mortality rate but also upon birth rates, not to speak of the effects of increases of income and of the organized strength of the working class on the length of the working week, the duration of training and the moment of retiring from the work process – are eliminated from the chain of reasoning, thereby leading to wrong and indeed absurd results.

If one compares Marx's own theory of wages to the opinions held by academic economists of his time, one sees at once the step forward which he accomplished. For he points out not only that labour-power, having been transformed by capitalism into a commodity, has a value which is objectively determined like the value of all other commodities, but also that the value of labour-power has a characteristic distinct from that of all other commodities – to wit that it is dependent on two elements: the *physiological* needs and the *historical-moral* needs of the working class.

This distinction is closely linked with the peculiar nature of labour-power: a commodity inseparable from and integrated with human beings, who are not only endowed with muscles and a stomach, but also with consciousness, nerves, desires, hopes and potential rebelliousness. The *physical capacity* to work can be measured by the calory inputs that have to compensate losses of energy. But the *willingness* to work at a given rhythm, a given intensity, under given conditions, with a given equipment of higher and higher value and increasing vulnerability, presupposes a level of consumption which is not simply equivalent to a sum-total of calories, but is also a function of what is commonly considered by the working class to be its 'current', 'habitual' standard of living.[64] Marx notes that these habitual standards differ greatly from country to country, and are generally higher in those countries which have an advanced, developed capitalist industry than in those which are still at pre-industrial levels, or are going through the throes of 'primitive' industrial capital accumulation.[65]

We thus reach an unexpected conclusion: according to this aspect of Marx's work, real wages would actually have to be higher in more advanced capitalist countries – and therefore also in more advanced stages of capitalism – than in less developed countries. This would also imply that they would tend to increase in time, as the level of industrialization increases. On the other hand, we have noted earlier that Marx explained fluctuation of wages during the trade cycle, that is of the price and not of the value of labour-power, as being governed essentially by the movements of the industrial reserve army. Real wages would tend to increase in times of boom and full employment and to decline in times of depression and large-scale unemployment. He indicated, however, that there was nothing automatic about this movement, and that the actual class *struggle* – including trade-union action, which he considered indispensable for this very reason – was the instrument through which workers could take advantage of more favourable conditions on the 'labour market' somewhat to increase their wages, whereas the main effect of depression was that it would weaken the resistence of the working class to wage-cuts.

---

[64] Lenin makes the point that with the development of capitalist industry there is a progressive increase in the workers' needs ('On the So-Called Market Question', in *Collected Works*, Vol. 1, pp. 106–7). See also Marx: 'This much, however, can even now be mentioned in passing, namely that the relative restriction on the sphere of the workers' consumption (which is only quantitative, not qualitative, or rather, only qualitative as posited through the quantitative) gives them as consumers ... an entirely different importance as agents of production from that which they possessed e.g. in antiquity or in the Middle Ages, or now possess in Asia' (*Grundrisse*, Pelican Marx Library, p. 283). Also ibid., pp. 186–7, 409.

[65] Karl Marx, 'Wages, Price and Profit', *Selected Works* in one volume, p. 223; *Capital*, Vol. 1, Chapter 22 (see below, pp. 702–5). The most categorical statement in that respect is to be found in *Theories of Surplus-Value*, Part II, pp. 16–17: 'The more productive one country is relative to another in the world market, the higher will be its wages, as compared with the other.'

But Marx stuck to his theory of value with regard to wages. Wages are the prices of the commodity labour-power. Like all other prices, they do not fluctuate at random, but around an axis which is the value of that commodity. The movements of wages that are influenced by the ups and downs of the trade cycle explain only short-term fluctuations: these have to be integrated within a wider analysis, explaining the long-term fluctuations of wages in function of the *changes in the value of labour-power.*

We can thus formulate Marx's theory of wages as an *accumulation of capital wage theory,* in opposition to the crude demographic wage theory of the Malthus–Ricardo–Lassalle school. Long-term movements of wages are a function of the accumulation of capital in a fivefold sense:

- Accumulation of capital implies a decline in value of a given basket of consumer goods included in the given standard of living of the working class (with the given reproduction costs of labour-power). In this sense, the development of capitalism tends to *depress the value* of labour-power, all other things remaining equal. Let us repeat: such a decline in the value of labour-power does not imply a decline, but only a stability, of real wages.
- Accumulation of capital implies a decline in the value and an expansion of the output (mass production) of consumer goods previously not included in the reproduction costs of labour-power. If objective and subjective conditions are favourable, the working class *can force* the inclusion of these goods into the accepted minimum standard of living, can expand the 'moral-historical' component of the value of labour-power, thereby *increasing its value.* This again does not happen automatically, but essentially as a result of the class struggle.
- Accumulation of capital will favour the increase in value of labour-power if the *long-term structural supply* of labour-power does not strongly exceed demand, or is even below demand. This explains why wages in the U.S.A. were from the beginning significantly higher than in Europe, why wages started rising significantly in the latter part of the nineteenth century in Europe as a result of massive overseas emigration of the reserve army of labour, and why persistent massive unemployment and underemployment in

the underdeveloped countries has implied a tendentially declining value of labour-power (often even accompanied by declining real wages) in the last two decades.
– Accumulation of capital forms the upper *barrier* which no increase in the value or the price of labour-power can break under capitalism. If and when the increase in the value of labour-power implies a strong decline in surplus-value, accumulation of capital slows down, large-scale unemployment reappears, and wages are 'readjusted' to a level compatible with capital accumulation. In other words, under capitalism, wages *can* fall to the point where the 'historical-moral' ingredient of the value of labour-power completely disappears, where they are actually reduced to the bare physiological minimum. They *cannot* rise to the point where the 'historical-moral' ingredient of the value of labour-power wipes out surplus-value as the source of capital accumulation.
– Accumulation of capital implies increased exploitation of the workers, including an increased *attrition of labour-power*, especially through intensification of the production process. But this in turn implies the *need for higher consumption* just to reproduce labour-power even physiologically. So one can say that, in this sense, capitalism increases the value of labour-power by making its exploitation more intensive.[66] One can especially find negative confirmation of this effect of the accumulation of capital on the value of labour-power. Once wages decline below a certain level (especially under the effects of wars or reactionary dictatorships), the productive effort of the workers will decline and labour-power will not be reconstituted to its full productive capacity, as a result of too low a level of wages.

How, then, has it been possible for so many writers, for so long, to have attributed to Marx a 'theory of absolute impoverishment

[66] We have noted that the *value* of labour-power is an objective category. This implies, among other phenomena, that an important increase in the intensity of the labour process leads to an increase in the value of labour-power, all other things remaining equal. A higher expenditure of labour-power implies the need for higher consumption, for example, food of higher calory content, to avoid an erosion of the capacity to work. Rosdolsky (op. cit., Vol. 1, p. 331) in this respect draws attention to a distinction made by Otto Bauer between 'physiological needs' born from the simple life process of the worker, and those needs born from the work process, the second expanding progressively compared with the first in step precisely with the growing intensification of work under capitalism.

of the workers under capitalism' which obviously implied a theory of tendential fall in the value not only of labour-power but even of real wages?[67] In the first place because Marx, in his youthful writings, did in fact hold such a theory – for example, in the Communist Manifesto.[68] But this was formulated before he had brought his theoretical understanding of the capitalist mode of production to its final, mature conclusion. It is only in the years 1857–8 that we have the birth of Marx's economic theory in its rounded, consistent form. After he had written *A Contribution to the Critique of Political Economy* and the *Grundrisse*, there was no longer a trace of any such historical trend towards absolute impoverishment in his economic analysis.

In the second place, because so many writers confuse Marx's treatment of the *value* of labour-power (which depends upon the *value* of the consumer goods the worker buys with his wages) with the category of real wages (determined by the *mass* of consumer goods his wages buy). Under capitalism, given the constant increase in the productivity of labour, these categories can move in opposite directions.[69]

---

[67] See, among others: Pareto, op. cit., p. 63; Ludwig von Mises, *Le Socialisme*, Paris, 1938, p. 438; Schumpeter, *Capitalism, Socialism and Democracy*, pp. 34–8; Karl Popper, *The Open Society*, Vol. 2, pp. 155–8; W. Arthur Lewis, *Theory of Economic Growth*, London, 1955, p. 298; Eric Roll, *A History of Economic Thought* (2nd edition), London, 1954, pp. 284, 293, etc. Two authors who, though they have studied Marx closely and call themselves Marxists, nevertheless repeat the same mistaken view are John Strachey in *Contemporary Capitalism*, London, 1956, pp. 101–8 and Fritz Sternberg in *Der Imperialismus*, Berlin, 1962, pp. 57–60. More objective are Paul M. Sweezy's account in *The Theory of Capitalist Development*, Oxford, 1943, pp. 87–92, and J. Steindl's in *Maturity and Stagnation in the American Economy*, Chapter 14, Oxford, 1952.

[68] 'Manifesto of the Communist Party', *The Revolutions of 1848*, Pelican Marx Library, 1973, pp. 74–5, 78.

[69] *Capital*, Vol. 1, Chapter 17 (see below, p. 659), contains the key formula in that respect: 'In this way it is possible, given increasing productivity of labour, for the *price* of labour-power to fall constantly and for this fall to be accompanied by a constant growth in the *mass* of the worker's means of subsistence' (our stress). In the same way, in a famous passage at the end of 'Wages, Price and Profit', Marx says that: '... consequently the general tendency of capitalistic production is not to raise but to sink the average standard of wages, or to push the *value of labour* to its minimum limit' (*Selected Works* in one volume, p. 225) and he adds that efforts to *increase wages* 99 times out of 100 only tend to maintain the value of labour-power. This whole argument applies to the trend of the *value* of labour-power, not to that of real wages.

In the third place, because two famous passages in *Capital* Volume 1 have been consistently misinterpreted.[70] In both these passages Marx does speak about 'increasing misery' and pauperism, and about 'accumulation of misery'. But the context indicates clearly that what he is referring to is the poverty and misery of the 'surplus population', of the 'Lazarus layer of the working class', that is, of the *unemployed or semi-employed poor*. Revealing studies on poverty in rich countries like the United States and Great Britain[71] have strikingly confirmed that the misery of these old-age pensioners, unemployed, sick, homeless, degraded or irregularly working lower layers of the proletariat *is* indeed a permanent feature of capitalism, including the capitalism of the 'welfare state'. The truth is simply that in passages such as these Marx uses formulations that are ambiguous and so lend weight to confusion on the question.

Does this mean that Marx did not formulate any theory of impoverishment of the working class, or that he made optimistic predictions about the general trend of working-class conditions under capitalism? This would of course be a complete paradox, in the light of what he wrote in Chapter 25 of *Capital* Volume 1. The point to be made is simply that this chapter – like all of Marx's mature writings on this subject – *is not concerned with movements of real wages at all*, any more than the chapters on value are about movements of market prices of commodities other than the commodity labour-power. This is clearly indicated in the very passage in question by Marx's statement that as capital accumulates the situation of workers becomes worse *irrespective of whether their wages are high or low*.[72]

What we in fact have here is a theory of a tendency towards *relative impoverishment* of the working class under capitalism in a double sense. Firstly, in the sense that productive workers tend to get a smaller part of the new value they produce: in other words there is a trend towards an increase in the rate of surplus-value. Secondly, in the sense that *even when wages rise* the needs of the workers as human beings are denied. This applies even to their additional consumer needs that grow out of the very increase in the productivity of labour which results from the accumulation of capital. One has only to think of the unfulfilled needs of workers in the fields of education, health, skill acquisition and differentiation, leisure, culture, housing, even in the richest capitalist countries of today, to see how this assumption remains accurate in spite of the so-called 'consumer society'. But it applies much more to the needs of the worker as a producer and a citizen – his need to develop a full personality, to become a rich and creative human being, etc.; these needs are brutally crushed by the tyranny of meaningless, mechanical, parcellized work, alienation of productive capacities and alienation of real human wealth.

---

[70] See below, Chapter 25, Section 4, pp. 797–8, 799.

[71] See, for example, Michael Harrington's already classic *The Other America*, Harmondsworth, 1963, and the equivalent British study by Brian Abel Smith and Peter Townsend, *The Poor and the Poorest*, London, 1963, which estimates that 14 per cent of the British population (7 million people!) were living in, or on the margin of, poverty twenty years after the establishment of the welfare state! To have revealed that such poverty is rooted in the *system* of wage-labour, and that no permanent elimination of it (i.e. a guaranteed standard of living for all human beings, irrespective of how much they work or indeed whether they work at all) is possible without upsetting the economic compulsion to sell the proletarian's labour-power, is one of Marx's most epoch-making discoveries and fundamental to his economic theory.

[72] See below, p. 799.

In addition to this law of *general relative* impoverishment of workers under capitalism, Marx also notes a trend towards *periodic absolute* impoverishment, essentially in function of the movement of unemployment. This is closely linked to the inevitability of cyclical fluctuations under capitalism, that is the inevitability of periodic crises of overproduction, or 'recessions' as they are called today with less provocative connotations.

There is also another aspect of Marx's theory of wages over which, for almost a century, controversy has raged. This is the question of the different values of 'skilled labour-power' and 'unskilled labour-power' (whether related or not to the question of whether Marx gives a satisfactory explanation of the fact that, according to his labour theory of value, skilled labour produces more value in an hour of work than unskilled labour). Starting with Böhm-Bawerk, some critics have claimed to discover here one of the basic inconsistencies in Marx's economic theory.[73] For if the greater productivity, in value terms, of skilled as opposed to unskilled workers is a function of the higher wages of the former, are we not back at Adam Smith's famous circular argument, in which the 'price of labour' determines the 'natural price' of goods but is in turn determined by the 'natural price' of one category of goods, so-called wage goods, that is food?

---

[73] For example. Böhm-Bawerk, op. cit., pp. 80–85; Pareto, op. cit., pp. 52–3; Schumpeter, *Capitalism, Socialism and Democracy*, p. 24, etc. An interesting discussion of this problem was recently provided by Bob Rowthorn, 'Skilled Labour in the Marxist System', in *Bulletin of the Conference of Socialist Economists*, Spring 1974.

But in fact Marx avoided such circular reasoning, contrary to what his critics mistakenly assume. He never explained the higher value content of an hour of skilled labour as compared to an hour of unskilled labour by the higher wages which skilled labour receives. This higher content is explained strictly in terms of the labour theory of value, by the additional labour costs necessary for producing the skill, in which are also included the total costs of schooling spent on those who do not successfully conclude their studies.[74] The higher value produced by an hour of skilled labour, as compared to an hour of unskilled labour, results from the fact that skilled labour participates in the 'total labour-power' (*Gesamtarbeitsvermögen*) of society (or of a given branch of industry) not only with its own labour-power but also with a fraction of the labour-power necessary to produce its skill. In other words, each hour of skilled labour can be considered as an hour of unskilled labour multiplied by a coefficient dependent on this cost of schooling.[75] Marx speaks in this context of 'composite labour' as against 'simple labour'. The skill, by analogy, can be compared to an additional tool, which is in itself not value-producing, but which transfers part of its own value into the value of the product produced by the skilled worker.

---

[74] This solution was first formulated by Hilferding in his answer to Böhm-Bawerk (op. cit., pp. 136–46), then worked out more explicitly by Hans Deutsch (*Qualifizierte Arbeit und Kapitalismus*, Vienna, 1904) and Otto Bauer ('Qualifizierte Arbeit und Kapitalismus', in *Die Neue Zeit*, 1905–6, No. 20). Deutsch differs from Hilferding in that according to Hilferding only the cost of production of skill (the work of the teacher, etc.) adds to the value of skilled labour-power, whereas for Deutsch the time spent by the apprentice (or student) himself while learning has to be added to those costs. Bauer supports Deutsch's thesis that the 'labour' of the apprentice (student) creates supplementary value and enters the process of value production of the skilled worker, but contrary to Deutsch (and together with Hilferding) he contends that this value increases the surplus-value produced by the skilled worker, not the value of his own labour-power. See on this controversy also Rubin, op. cit., pp. 159–71, and Rosdolsky, op. cit., Vol. 2, pp. 597–614.

10. MARX'S THEORY OF MONEY

Marx's attempt to formulate his own theory of money originates in a significant flaw in Ricardo's economic system.[76] While Ricardo adheres to a strict labour theory of value concerning commodities, he contends that this is true for gold only if the quantity in circulation remains in exact proportion to the mass and prices of other commodities. Increases or decreases in this money circulation would provoke an increase or decrease in commodity prices and this in turn would provoke a further decrease or increase in the value of gold. Marx tries to overcome this inconsistency by integrating his theory of money into his general explanation of value, value production and autonomous value circulation (money circulation, capital circulation), on the basis of a rigorous application of the labour theory of value.

As with the theory of value, the most important aspect of this monetary theory is the qualitative one, which has hitherto received too little attention from either the critics or the disciples of Marx. The fact that social labour, in a society based upon generalized commodity production, is fragmented into many segments of private labour executed independently of each other leads, as we have seen, to the result that its social character can only be recognized *post festum*, through the sale of the commodity and depending upon the amount of equivalent it receives in this sale. The social character of the labour embedded in the commodity, therefore, can only appear as *a thing* outside the commodity – that is, money. The fact that relations between human beings appear under capitalism (generalized commodity production) as relations between things – a phenomenon which Marx analysed at length in the fourth section on 'The Fetishism of the Commodity' of Chapter 1 of *Capital* Volume 1 (see pp. 163–77 below) – should, therefore, not be understood in the sense that people under capitalism, being in the grip of false consciousness, have the illusion of being confronted with things when in reality they are confronted with specific social relations of production. It is also an objective necessity and compulsion. Under conditions of generalized commodity production, social labour *cannot* be immediately recognized otherwise than through its exchange against money. The circulation of commodities cannot but produce its own counterpart in the circulation of the medium of exchange, money.[77] Money is the necessary materialization of abstract social labour: that is the qualitative determinant in Marxist monetary theory.

---

[76] Karl Marx, *A Contribution to the Critique of Political Economy*, pp. 170–79.

It is by losing sight of this fundamental social nature of money, rooted in specific social relations of production, that so many authors, including Marxist ones,[78] have been tempted to give money, and money-creation, functions which they cannot fulfil in a society based upon private property. To assume an 'automatic' realization of the exchange-value of commodities through the creation of an 'adequate' volume of money presupposes that that value is pre-established, that all labour expended on the production of these commodities was socially necessary labour. In other words, it presupposes that there exists a permanent equilibrium of supply with effective demand and, therefore, that there is no commodity production at all but *a priori* adaptation of production to consciously registered needs. Under capitalism, including monopoly capitalism, this can never be achieved.

Money born from the process of exchange, from the circulation of commodities, can realize the value of these commodities only because it itself has value, because it itself is a commodity produced by socially necessary abstract labour. Marx's theory of money is, therefore, above all a *commodity theory of money* in which the monetary standards (precious metals) enter the process of circulation with an intrinsic value of their own. From that point of view, Marx must reject any quantity theory of money applied to money

---

77. See Marx's footnote at the beginning of Chapter 3 on Money (below, p. 188): 'The question why money does not itself directly represent labour-time, so that a piece of paper may represent, for instance, *x* hours' labour, comes down simply to the question why, on the basis of commodity production, the products of labour must take the form of commodities. This is obvious, because their taking the form of commodities implies their differentiation into commodities [on the one hand] and the money commodity [on the other]. It is also asked why private labour cannot be treated as its opposite, directly social labour.'

78. For example, Hilferding's proposal (*Das Finanzkapital*, pp. 29–30) for a category called 'socially necessary value of circulation' (*gesellschaftlich notwendiger Zirkulationswert*), established by dividing the sum of *values* of all commodities by the velocity of circulation of money. Hilferding does not notice the incongruity of dividing quantities of value, i.e. socially necessary labour quanta, by the velocity of circulation media. Only prices (the *monetary* expression of value) can, of course, be so divided. Commodities cannot enter the circulation process except with (preliminary) prices. (See *A Contribution to the Critique of Political Economy*, pp. 66–8.)

based upon a gold or gold-and-silver basis. When, with a given velocity of circulation, a given amount of gold has a value higher than that of the total mass of commodities against which it exchanges itself, it can no more 'lose' value (that is, provoke an increase of prices through abundance of bullion) in the circulation process than any other commodity. What happens is simply that part of it will be withdrawn from circulation and hoarded, until such time as the need for circulation again increases.

But if such a commodity theory of money implies a straight rejection of the quantity theory, as long as money is directly based upon precious metals, it points in the opposite direction as soon as we are faced with paper bank notes which function in reality as *representatives* of, and tokens for, precious metals. In this case, quite independently of whether or not there is legal convertibility of paper into gold,[79] emission of paper money to the amount which, at a given value of gold and a given velocity of circulation of the bank notes, enables it to realize the prices of all the commodities in circulation, will leave these prices unaffected. But if this amount of paper money in circulation is doubled at its face value, all other things remaining equal, prices expressed in that currency will also double, not in contradiction with, but in application of, the labour theory of value. To simplify, if we presume that each unit of gold circulates only once a year, the equation 1,000,000 tons of steel = 1,000 kilos of gold means that the same quantity of socially necessary abstract labour (say 100,000,000 man hours) has been necessary to produce the respective quantities of steel and gold. If £1,000,000 represents 1,000 kilos of gold, then the fact that the price of 1 ton of steel is £1 is just a straight expression of the equality in value (in quantities of abstract labour) between 1 ton of steel and 1 kilo of gold. But if, through additional issuing of paper money, 1,000 kilos of gold is now represented by £2,000,000 instead of £1,000,000, then, all other things remaining equal, the price of steel will rise from £1 to £2 in strict application of the labour theory of value.

This does not mean that, with regard to paper money, Marx was the proponent of any mechanistic quantity theory. There is an evident analogy between his theory and the traditional forms of the quantity of money; but this analogy is limited by two essential factors. In the first place, for Marx, with paper money as with metallic money, it is the movement of the value of commodities, that is fluctuations of material production and of productivity of labour, which remains the *primum movens* of price fluctuations, not the ups and downs of the quantity of paper money in circulation.[80] In that respect, in *Capital* Volume 3, Marx examines the need to increase money circulation at the moment of the outbreak of the crisis, and he sharply criticizes the role which the Bank of England played, through the application of the 'currency principle', in accentuating money panics and monetary crises as accelerators of crises of overproduction when these coincided with an outflow of gold from England. In the same way, however, he denied any possibility of preventing recessions by issuing additional money.[81]

---

[79] This was, for example, the case in France after its military defeat by Germany in 1870–71, when the payment of a heavy gold war indemnity to the Reich imposed a temporary suspension of convertibility of the franc without provoking any inflationary price movement in the Third Republic.

In the second place, Marx understood perfectly that the dialectical interrelationship of all the elements of a mechanistic quantity theory equation excludes the possibility of simply deriving conclusions from independent variations of a single one of these elements. He knew, for example, that the velocity of circulation of money was co-determined by the trade cycle, and could not be considered stable in a given phase when only the quantity of money was supposed to change. But an analysis of his opinions on all these subjects as well as a short comment on his whole theory of the role of money in the trade cycle and of fictitious capital has its place in the introduction to Volume 3 rather than Volume 1 of *Capital.*

With the development and generalization of commodity production, money becomes more and more transformed into money capital. It is more and more replaced by 'monetary signs' in the process of circulation, and becomes more and more transformed from a means of exchange into a means of payment, that is into the counterpart of debts, into an instrument of credit. But in examining the credit role of money Marx maintains a rigorous adherence to the labour theory of value, so that his whole economic system is thoroughly 'monistic'. Money as the general equivalent of the exchange value of all commodities and money as the means to settle debts (resulting out of the generalization of sales on credit) are both claims on a given fraction of the total labour expenditure of society in a given period. Whatever the 'nominal' value of the currency, and whatever the 'standard of measurement' of prices, it is obviously impossible to distribute more labour quantities than have been produced and stocked within the same period of time. On the other hand, given the very nature of commodity production, no general increase of money circulation (no increase of 'aggregate demand') can in the long run prevent the eventuality that a whole series of commodities produced will not meet the 'specific demand' they need to allow their proprietors to realize at least the average rate of profit. Technological changes, differences in productivity between different plants and firms, changes in real wages and in the structure of consumer expenditures, changes in the rate of profit entailing changes in the direction and structure of investment: all these complex movements which make the trade cycle and periodic recessions possible and indeed unavoidable under conditions of generalized commodity production cannot be eliminated by manipulation of currency volume or currency units. Experience since Marx's death, and especially since the 'Keynesian revolution', fully confirms the correctness of this diagnosis, although it also confirms that, under specific conditions and within specific limits, monetary policies can reduce the *amplitude* of economic fluctuations, a fact of which Marx was perfectly aware.[82]

---

[80] Except in cases of galloping inflation.

[81] See Karl Marx, *Capital*, Vol. 3, p. 503. In the margin of the first edition of *Capital* Vol. 1, Marx added a note to Chapter 3, converted by Engels in subsequent editions into a footnote (see below, p. 236n.), in which he indicated the distinction between monetary crises as expressions of general crises of overproduction, and autonomous monetary crises.

Marx's short comments on the dual nature of gold, as the basis 'in the last resort' of all paper money systems and as the only possible 'world currency' acceptable for final settlement of accounts between the central banks (and bourgeois classes) of different nations, make especially interesting reading today, when the Bretton Woods monetary system has broken down because of the inconvertibility of the dollar into gold. It is interesting to note that Marx, while rejecting all theories which explain the 'value' of money by convention or state compulsion,[83] does relate this role of gold as a means of final settlement of accounts on an international scale to the specific role of the bourgeois state. Among the functions of the state is that of creating the 'general conditions for capitalist production'. A coherent and accepted currency cer-

82. Karl Marx, *Capital*, Vol. 3, Chapter 34, especially p. 539.

83. Karl Marx, *Grundrisse*, p. 165; *A Contribution to the Critique of Political Economy*, p. 116.

tainly belongs to these 'general conditions'. Paper money with a fixed rate of exchange (*Zwangskurs*) can be imposed only *through the authority of the state* within given limits.[84] But where this authority is absent, proprietors of commodities cannot be forced to accept in exchange for their goods paper money whose rate they consider inflated. 'Paper gold' as a universal means of exchange and payment on the world market presupposes, therefore, a world government, in other words the absence of inter-imperialist competition and, therefore, in the last analysis the withering away of private property. To expect such a situation to occur under capitalism is utopian.

Marx's theory of money has been much less analysed, criticized and discussed by later Marxists than other parts of his economic theory.[85] An interesting discussion did, however, occur on the eve of the First World War between Hilferding, Kautsky and Varga, on the possibility of deducing from the *value* of commodities a 'socially necessary volume of money' – a hypothesis which is obviously mistaken since it confuses the *value* of commodities with their *price*.[86] Varga, moreover, in a series of polemics which were continued in the early twenties, persisted in maintaining that, as central banks bought gold at a fixed price, the fluctuations of the intrinsic value of gold would not influence the general level of prices, but only govern the ups and downs of the differential rent commanded by gold mines with a productivity above the level allowing the average rate of profit at the given price of gold.[87] Subsequent developments, especially in the last four or five years, have confirmed that both these attempted corrections of Marx's theory of money were unfounded and wrong.

[84] Karl Marx, *Grundrisse*, pp. 121–35; *A Contribution to the Critique of Political Economy*, pp. 116, 119–22, 149–53.

[85] A rare exception is the book by Bruno Fritsch, *Die Geld- und Kredittheorie von Karl Marx*, Frankfurt, 1968, which, although very critical, recognizes Marx's merit as the 'first real theoretician of credit'. Much weaker was an earlier book by H. Block, *Die Marxsche Geldtheorie*, Jena, 1926.

This discussion continued between Varga and E. Ludwig in 1923, in the theoretical organ of the KPD, *Die Internationale*.

II. *CAPITAL* AND THE DESTINY OF CAPITALISM

It is above all through its integration of theory and history that Marxism manifests its superiority in the economic domain over classical and neo-classical political economy. It is through its ability to foresee correctly long-term trends of capitalist development, including the main inner contradictions of the capitalist mode of production which propel this long-term development forward, that *Capital* continues to fascinate friend and foe alike. Those who, generation after generation, continue to accuse Marx of 'unscientific' *parti pris* or speculative excursions into the realms of prophecy[88] cannot escape the burden of proof. It is up to them to account for the mysterious fact that a thinker according to them so devoid of analytical tools should have been able unfailingly to work out the long-term laws of motion that have determined the development of capitalism for a century and a half.

Apart from the so-called law of increasing absolute impoverishment of the working class wrongly attributed to Marx, the aspect of the latter's theoretical conclusions concerning the capitalist mode of production which has been most consistently under attack since *Capital* Volume 1 first appeared has been the so-called 'theory of the inevitable collapse of capitalism' (*Zusammenbruchstheorie*). First strongly challenged by the Bernsteinian 'revisionists' within the socialist movement, and only weakly defended by most orthodox Marxists of the epoch,[89] the theory has been exposed to ridicule by a monotonous succession of authors in the last decades. All have asked the ritual rhetorical question: has not the capitalist mode of production shown a capacity of adaptation and self-reform far beyond anything which Marx foresaw?[90]

---

[88] The most outstanding example is that of Popper, *The Open Society and its Enemies*, Vol. 2. See also, by the same author, *Conjectures and Refutations*, pp. 336–46, quoted above.

[89] For Bernstein's questioning of the breakdown theory see, for example, op. cit., pp. 113–28. For a very mild reply see Heinrich Cunow, 'Zur Zusammenbruchstheorie' in *Die Neue Zeit*, 1898–9, I, pp. 424–30. In *Das Finanzkapital* Hilferding already raised the theoretical possibility of an 'organized' capitalism without crises, through the operations of a 'general cartel' (op. cit., p. 372).

[90] See, for example, Tugan-Baranovsky, op. cit., pp. 236–9; Schumpeter, *Capitalism, Socialism and Democracy*, p. 42; Popper, *The Open Society and its Enemies*, Vol. 2, p. 155 et al.; C.A.R. Crosland, *The Future of Socialism*,

Arguments along these lines usually contain a basic flaw: they try to prove too much. They contend that capitalism has survived so many crises that nobody can seriously challenge its capacity to survive future ones. But at the same time they also contend that the present economic system in the West cannot any longer be characterized as 'capitalist'; and that through successive self-reform and adaptation, in order to overcome crises which threatened to wreck it, capitalism has transformed itself into a new social organization of the economy. This they most often characterize by the term 'mixed economy', although a host of other formulas such as 'managerial capitalism', 'organized capitalism', 'managerial society', 'technostructure rule', etc. have at times been devised to describe it.[91]

But *Capital* is not simply a powerful tool for understanding the great lines of world development since the industrial revolution. It also furnishes us with a clear and unequivocal definition of what the capitalist mode of production essentially represents. Capitalism is neither a society of 'perfect competition', nor a society of 'increasing pauperism', nor a society where 'private entrepreneurs rule the factories', nor even a society in which 'money is the one and only master'. Vague and imprecise definitions of this type, which allow evasion of the *basic* issues, lead to endless confusion about the relationship of today's economic system in the West with the economic system analysed by *Capital*.[92] *Capital* shows that the capitalist mode of production is fundamentally determined by

---

London, 1956, pp. 3–5, etc. An interesting and voluminous anthology of texts related to the *Zusammenbruchstheorie* has been published in Italy by Lucio Colletti and Claudio Napoleoni, *Il futuro del capitalismo – crollo o sviluppo ?*, Bari, 1970.

[91] It is impossible to list all the important authors who have evolved this type of analysis. It is sufficient to indicate the main trends: that of James Burnham's 'Managerial Revolution'; that of the social democrats and Samuelson's 'mixed economy' (see Crosland, op. cit., pp. 29–35); that of Robin Morris's 'Managerial Capitalism'; and that of Galbraith's 'technostructure' (*The New Industrial State*) which follows, perhaps unknowingly, the analysis of the German Social Democrat Richard Loewenthal (writing under the pen-name Paul Sering), in *Jenseits des Kapitalismus*, Nuremberg, 1946.

[92] Here a characteristic statement by Popper: 'How utterly absurd it is to identify the economic system of the modern democracies with the system Marx called "capitalism" can be seen at a glance, by comparing it with his ten-point programme for the communist revolution' (in the Communist Manifesto of 1848) (*The Open Society and its Enemies*, Vol. 2, p. 129).

three conditions and three only: (1) the fact that the mass of producers are not owners of the means of production in the economic sense of the word, but have to sell their labour-power to the owners; (2) the fact that these owners are organized into separate firms which compete with each other for shares of the market on which commodities are sold, for profitable fields of investment for capital, for sources of raw materials, etc. (that is, the institution of private property in the economic sense of the word); (3) the fact that these same owners of the means of production (different firms) are, therefore, compelled to extort the maximum surplus-value from the producers, in order to accumulate more and more capital – which leads, under conditions of generalized commodity production and generalized alienation, to constantly growing mechanization of labour, concentration and centralization of capital, growing organic composition of capital, the tendency for the rate of profit to fall, and periodically recurrent crises of over-production.

If these are the criteria, there can be no question that Western society is still capitalist; that wage-labour and capital are still the two antagonistic classes of society; that accumulation of capital is more than ever the basic motive force of that society; and that the extortion and realization of private profit governs the basic drive of separate firms.

Such aspects of contemporary Western society as the fact that some of these firms are nationalized; that there is growing state intervention in the economy; that competition has become 'imperfect' (that it is no longer essentially fought by cutting prices, but rather by reducing production costs and increasing distribution and sales); that workers have strong trade unions (except when, under conditions of violent social crisis, bourgeois democratic freedoms are abolished) and that their standard of living has risen far more than Marx expected it to rise – all this in no way abolishes or reduces the relevance of the basic structural features of capitalism, as defined by *Capital*, from which all the basic laws of motion of the system flow. These basic laws of motion thus continue to remain valid.

Without courting paradox one could even contend that, from a structural point of view, the 'concrete' capitalism of the final quarter of the twentieth century is much closer to the 'abstract' model of *Capital* than was the 'concrete' capitalism of 1867, when Marx finished correcting the proofs of Volume 1. Firstly, because the intermediate class of small independent producers, proprietors of their own means of production, which was still a significant social layer a century ago, has today nearly been eroded out of existence; dependent wage and salary earners, compelled to sell their labour-power, now amount to over 80 per cent of the economically active population in most Western countries and in several to over 90 per cent. Secondly, because concentration and centralization of capital has led to a situation where not only do a couple of hundred giant corporations dominate the economy of each imperialist country, but a few hundred multi-national corporations also concentrate in their hands one third of all the wealth of the capitalist *world* economy. Thirdly, because the productivity and the objective socialization of labour have increased to such an extent that production of value for private enrichment has become absurd beyond anything Marx could have foreseen a century ago and the world cries out so compellingly for a planned husbanding of resources to satisfy needs on the basis of consciously and democratically chosen priorities that even opponents of socialism cannot fail to understand the message.[93]

Why then, one might ask, have the expropriators not yet become the expropriated, and why does capitalism still survive in the highly industrialized countries? The answer to that question would involve a detailed critical review of twentieth-century political and social history. But the whole point is, of course, that Marx never predicted any sudden and automatic collapse of the capitalist system in one 'final' crisis, due to a single economic 'cause'. In the famous Chapter 32 of *Capital* Volume 1, 'The Historical Tendency of Capitalist Accumulation', Marx describes economic tendencies provoking a reaction from social forces. The growth of the proletariat, of its exploitation, and of organized revolt against that exploitation, are the main levers for the overthrow of capitalism. Centralization of the means of production and objective socialization of labour create the economic preconditions for a society based upon collective property and free co-operation by associated producers. But they do not automatically produce such a society on some universal day of victory. They have to be consciously utilized, at privileged moments of *social* crisis, to bring about the revolutionary overthrow of the system.

Marx was as far removed from any fatalistic belief in the automatic effects of economic determinism as any social thinker could be. He repeated over and over again that men made and had to make their own history, only not in an arbitrary way and independently from the material conditions in which they found themselves.[94] Any theory of the collapse of capitalism, therefore, can only present itself as Marxist if it is a theory of conscious overthrow of capitalism, that is, a theory of socialist revolution.[95] Chapter 32, at the end of *Capital* Volume 1, only indicates in very general terms how and why objective inner contradictions of the capitalist mode of production make this overthrow both possible and necessary. The rest has to result, in Marx's words, from the growth of 'the revolt of the working class, a class constantly increasing in numbers, and trained, united and organized by the very mechanism of the capitalist process of production'.

---

[93] See, for example, the reaction of scholars like Barry Commoner (*The Closing Cycle*, London, 1972) to the ecological crisis.

In other words, between the growing economic contradictions of the capitalist mode of production on the one hand, and the collapse of capitalism on the other hand, there is a necessary mediation: the development of the class consciousness, organized strength and capacity for revolutionary action of the working class (including revolutionary leadership). *That* chapter of Marxist theory is not incorporated into *Capital*. Perhaps Marx intended to discuss it in the book on the State which he wanted to write but never came even to draft. At all events, he left no systematic exposition of his thought in this respect, although many ideas on the subject are to be found scattered throughout his articles and letters. It was up to his most gifted followers, foremost among them Lenin, Trotsky and Rosa Luxemburg, to deal systematically with what one might call 'the Marxist theory of the subjective factor'.

---

[94] See, for instance, the end of Marx's remarkable letter to Friedrich Bolte of 23 November 1871 (*Selected Correspondence*, pp. 269–71) in which he explains the necessity for previous organization of the working class in order for it to be able to challenge the bourgeoisie for political power, and the fact that without such systematic education through propaganda, agitation and action, the working class remains a captive of bourgeois politics.

[95] Rosa Luxemburg admirably synthesized the contradictory trends as early as 1899: 'The production relations of capitalist society approach more and more the production relations of socialist society. But on the other hand, its political and juridical relations [and, one might add, their ideological reflections in the minds of men as well] establish between capitalist society and socialist society a steadily rising wall. This wall is not overthrown but on the contrary strengthened and consolidated by the development of social reforms and the course of [bourgeois parliamentary] democracy' ('Reform or Revolution', in Mary Alice Waters (ed.), *Rosa Luxemburg Speaks*, New York, 1970, p. 57).

The survival of capitalism to this day in the most industrialized countries has certainly given it a life-span far beyond what Marx expected. But this is not because the system has developed in essentially other directions than those predicted by *Capital*. Nor is it because it has been able to avoid a periodic repetition of explosive social crises. On the contrary, since the Russian revolution of 1905, and certainly since the outbreak of the First World War, such crises have become recurrent features of contemporary history.

In the course of such crises, capitalism has indeed been overthrown in many countries, Russia and China being the most important. But contrary to what Marx expected, this overthrow occurred not so much where the proletariat was most strongly developed numerically and economically, as a result of the greatest possible extension of capitalist industry, that is, in those countries which also have a powerful bourgeois class. It occurred rather in those countries where the bourgeoisie was weakest and where, therefore, the political relationship of forces was favourable for a young proletariat capable of gaining the support of a strongly rebellious peasantry. This historical detour can be understood only if one integrates into the analysis two key factors: on the one hand, the development of imperialism and its effect on the large part of the human race which lives in socially and economically underdeveloped societies (the law of uneven and combined development); on the other hand, the interrelationship between the lack of revolutionary experience on the part of the Western working class during the long period of 'organic growth' of imperialism (1890–1914) and the growing reformism and integration of social democracy into bourgeois society and the bourgeois state which were responsible for the failure of the first large-scale revolutionary crises in the West, in 1918–23 (above all in Germany and Italy). As a result of this failure, the victorious Russian revolution itself became isolated, and the international working-class movement went through the dark interlude of Stalinism, from which it only slowly began to emerge in the nineteen-fifties. This brings us back to what I have called the Marxist theory of the subjective factor – and incidentally explains why, after the rich flowering of Marxist economic theory in the period 1895–1930, a quarter of a century of almost total stagnation occurred in that field too.

The debate around the *Zusammenbruchstheorie* has suffered from a confusion between two different questions: the question whether the replacement of capitalism by socialism is inevitable (an inevitable result of the inner economic contradictions of the capitalist mode of production); and the question whether, in the absence of a socialist revolution, capitalism would live on for ever. A negative answer to the first question in no way implies a positive one to the second. Indeed, classical Marxists, following the young Marx, formulated their prognosis in the form of a dilemma: socialism or barbarism.

The social catastrophes which mankind has witnessed since Auschwitz and Hiroshima indicate that there was nothing 'romantic' in such a prognosis, but that it expressed a clear insight into the terrifying destructive potential of exchange-value production, capital accumulation, and the struggle for personal enrichment as ends in themselves. The concrete mechanics of the economic breakdown of capitalist economy may be open to conjecture. The interrelationship of the downturn of value production (decline of the total number of labour hours produced as a result of semi-automation), of the increasing difficulty of realizing surplus-value, of increasing output of waste not entering the reproduction process, of increasing depletion of national resources and, above all, of long-term decline of the rate of profit, is still far from clear.[96] But a very strong case can be made for the thesis that there are definite limits to the adaptability of capitalist relations of production, and that these limits are being progressively attained in one field after another.

It is most unlikely that capitalism will survive another half-century of the crises (military, political, social, monetary, cultural) which have occurred uninterruptedly since 1914. It is most probable, moreover, that *Capital* and what it stands for – namely a scientific analysis of bourgeois society which represents the proletariat's class consciousness at its highest level – will in the end prove to have made a decisive contribution to capitalism's replacement by a classless society of associated producers.

---

[96] I shall return to this whole subject, and especially to the relationship of the breakdown controversy to the tendency for the average rate of profit to decline, in the introduction to *Capital*, Vol. 3.

ERNEST MANDEL

Translator's Preface

The original English translation of the first volume of *Capital*, by Samuel Moore and Edward Aveling, was edited by Engels. His letters show that he took the task very seriously, and, as Marx's friend and collaborator for forty years, he was certainly in a position to make the translation an authoritative presentation of Marx's thought in English.

So why is a new translation necessary? Firstly, the English language itself has changed. A translation made in the nineteenth century can hardly survive this change intact. Think only of the pejorative sense the word 'labourer' has taken on, making its replacement by 'worker' essential.

Secondly, Engels always tried to spare Marx's readers from grappling with difficult passages. In this, he was following his friend's example. In the Postface to the French edition, written in 1875, Marx explains that he has revised the French text in order to make it 'more accessible to the reader', even though the rendering presented to him by Roy was 'scrupulously exact', referring in justification to the French public's impatience with theoretical discussion. In 1975, however, after the immense effort of critical investigation into Marxism made in the last few decades, and the publication of hitherto unavailable texts, it is no longer necessary to water down *Capital* in order to spare the reader (who was, in any case, generally put off by the bulk of the book rather than its difficulty). Hence whole sentences omitted by Engels can be restored, and theoretical difficulties, instead of being swept under the carpet, can be exposed to the daylight, in so far as the English language is capable of this. This comment relates above all to German philosophical terms, used repeatedly by Marx in *Capital*, as indeed elsewhere. In translating these, I have tried not to prejudge the philosophical questions, the question of Marx's relation to Hegel and that of the relation between his philosophy and his political economy, but rather to present a text which would permit the reader to form his own view.

Thirdly, it is generally agreed that Marx was a master of literary German. A translation which overlooks this will not do justice to his vivid use of the language and the startling and strong images which abound in *Capital*. In my translation, I have always tried to bear this element in mind. How successfully, the reader must judge.

BEN FOWKES

NOTE

In compiling the editorial footnotes, indicated by asterisks etc., the translator has derived much assistance from the *Marx-Engels Werke* (*MEW*) edition of *Capital*.

Preface to the First Edition

This work, whose first volume I now submit to the public, forms the continuation of my book *Zur Kritik der Politischen Ökonomie*, published in 1859.* The long pause between the first part and the continuation is due to an illness of many years' duration, which interrupted my work again and again.

The substance of that earlier work is summarized in the first chapter† of this volume. This is done not merely for the sake of connectedness and completeness. The presentation is improved. As far as circumstances in any way permit, many points only hinted at in the earlier book are here worked out more fully, while, conversely, points worked out fully there are only touched upon in this volume. The sections on the history of the theories of value and of money are now, of course, left out altogether. However, the reader of the earlier work will find new sources relating to the history of those theories in the notes to the first chapter.

Beginnings are always difficult in all sciences. The understanding of the first chapter, especially the section that contains the analysis of commodities, will therefore present the greatest difficulty. I have popularized the passages concerning the substance of value and the magnitude of value as much as possible.‡[1] The

[1] This is the more necessary, in that even the section of Ferdinand Lassalle's work against Schulze-Delitzsch in which he professes to give 'the intellectual quintessence' of my explanations on these matters, contains important mistakes. If Ferdinand Lassalle has borrowed almost literally from my writings, and without any acknowledgement, all the general theoretical propositions in

† The first chapter in the first edition. In subsequent editions this was expanded to three chapters, as in this edition.

‡ In this edition, numbered footnotes are Marx's own. Those marked by asterisks etc. are the translator's.

value-form, whose fully developed shape is the money-form, is very simple and slight in content. Nevertheless, the human mind has sought in vain for more than 2,000 years to get to the bottom of it, while on the other hand there has been at least an approximation to a successful analysis of forms which are much richer in content and more complex. Why? Because the complete body is easier to study than its cells. Moreover, in the analysis of economic forms neither microscopes nor chemical reagents are of assistance. The power of abstraction must replace both. But for bourgeois society, the commodity-form of the product of labour, or the value-form of the commodity, is the economic cell-form. To the superficial observer, the analysis of these forms seems to turn upon minutiae. It does in fact deal with minutiae, but so similarly does microscopic anatomy.

With the exception of the section on the form of value, therefore, this volume cannot stand accused on the score of difficulty. I assume, of course, a reader who is willing to learn something new and therefore to think for himself.

The physicist either observes natural processes where they occur in their most significant form, and are least affected by disturbing influences, or, wherever possible, he makes experiments under conditions which ensure that the process will occur in its pure state. What I have to examine in this work is the capitalist mode of production, and the relations of production and forms of intercourse [*Verkehrsverhältnisse*] that correspond to it. Until now, their *locus classicus* has been England. This is the reason why England is used as the main illustration of the theoretical developments I make. If, however, the German reader pharisaically shrugs his shoulders at the condition of the English industrial and agricultural workers, or optimistically comforts himself with the thought that in Germany things are not nearly so bad, I must plainly tell him: *De te fabula narratur!**

Intrinsically, it is not a question of the higher or lower degree of

---

his economic works, for example those on the historical character of capital, on the connection between the relations of production and the mode of production, etc., etc., even down to the terminology created by me, this may perhaps be due to purposes of propaganda. I am of course not speaking here of his detailed working-out and application of these propositions, which I have nothing to do with.

---

*'The tale is told of you' (Horace, *Satires*, Bk I, Satire 1).

development of the social antagonisms that spring from the natural laws of capitalist production. It is a question of these laws themselves, of these tendencies winning their way through and working themselves out with iron necessity. The country that is more developed industrially only shows, to the less developed, the image of its own future.

But in any case, and apart from all this, where capitalist production has made itself fully at home amongst us,* for instance in the factories properly so called, the situation is much worse than in England, because the counterpoise of the Factory Acts is absent. In all other spheres, and just like the rest of Continental Western Europe, we suffer not only from the development of capitalist production, but also from the incompleteness of that development. Alongside the modern evils, we are oppressed by a whole series of inherited evils, arising from the passive survival of archaic and outmoded modes of production, with their accompanying train of anachronistic social and political relations. We suffer not only from the living, but from the dead. *Le mort saisit le vif !*†

The social statistics of Germany and the rest of Continental Western Europe are, in comparison with those of England, quite wretched. But they raise the veil just enough to let us catch a glimpse of the Medusa's head behind it. We should be appalled at our own circumstances if, as in England, our governments and parliaments periodically appointed commissions of inquiry into economic conditions; if these commissions were armed with the same plenary powers to get at the truth; if it were possible to find for this purpose men as competent, as free from partisanship and respect of persons as are England's factory inspectors, her medical reporters on public health, her commissioners of inquiry into the exploitation of women and children, into conditions of housing and nourishment, and so on. Perseus wore a magic cap so that the monsters he hunted down might not see him. We draw the magic cap down over our own eyes and ears so as to deny that there are any monsters.

Let us not deceive ourselves about this. Just as in the eighteenth century the American War of Independence sounded the tocsin for the European middle class, so in the nineteenth century the American Civil War did the same for the European working class. In England the process of transformation is palpably evident. When it has reached a certain point, it must react on the Continent.

* i.e. amongst the Germans. † 'The dead man clutches onto the living!'

There it will take a form more brutal or more humane, according to the degree of development of the working class itself. Apart from any higher motives, then, the most basic interests of the present ruling classes dictate to them that they clear out of the way all the legally removable obstacles to the development of the working class. For this reason, among others, I have devoted a great deal of space in this volume to the history, the details, and the results of the English factory legislation. One nation can and should learn from others. Even when a society has begun to track down the natural laws of its movement – and it is the ultimate aim of this work to reveal the economic law of motion of modern society – it can neither leap over the natural phases of its development nor remove them by decree. But it can shorten and lessen the birth-pangs.

To prevent possible misunderstandings, let me say this. I do not by any means depict the capitalist and the landowner in rosy colours. But individuals are dealt with here only in so far as they are the personifications of economic categories, the bearers [*Träger*] of particular class-relations and interests. My standpoint, from which the development of the economic formation of society is viewed as a process of natural history, can less than any other make the individual responsible for relations whose creature he remains, socially speaking, however much he may subjectively raise himself above them.

In the domain of political economy, free scientific inquiry does not merely meet the same enemies as in all other domains. The peculiar nature of the material it deals with summons into the fray on the opposing side the most violent, sordid and malignant passions of the human breast, the Furies of private interest. The Established Church, for instance, will more readily pardon an attack on thirty-eight of its thirty-nine articles than on one thirty-ninth of its income. Nowadays atheism itself is a *culpa levis*,* as compared with the criticism of existing property relations. Nevertheless, even here there is an unmistakable advance. I refer, as an example, to the Blue Book published within the last few weeks: 'Correspondence with Her Majesty's Missions Abroad, Regarding Industrial Questions and Trades' Unions'. There the representatives of the English Crown in foreign countries declare in plain language that in Germany, in France, in short in all the civilized states of the European Continent, a radical change in the existing relations between capital and labour is as evident and inevitable as in England. At the same time, on the other side of the Atlantic Ocean, Mr Wade, Vice-President of the United States, has declared in public meetings that, after the abolition of slavery, a radical transformation in the existing relations of capital and landed property is on the agenda. These are signs of the times, not to be hidden by purple mantles or black cassocks. They do not signify that tomorrow a miracle will occur. They do show that, within the ruling classes themselves, the foreboding is emerging that the present society is no solid crystal, but an organism capable of change, and constantly engaged in a process of change.

---

* 'Venial sin'.

The second volume of this work will deal with the process of the circulation of capital (Book II) and the various forms of the process of capital in its totality (Book III), while the third and last volume (Book IV) will deal with the history of the theory.*

I welcome every opinion based on scientific criticism. As to the prejudices of so-called public opinion, to which I have never made concessions, now, as ever, my maxim is that of the great Florentine:

'*Segui il tuo corso, e lascia dir le genti.*'†

Karl Marx

London, 25 July 1867

---

*Books II and III were issued by Engels after Marx's death as separate volumes, and are referred to below as Volumes 2 and 3, as they are generally known. This would have made Book IV Volume 4, but the manuscript for this was eventually published by Kautsky as *Theories of Surplus-Value.*

†'Go on your way, and let the people talk.' Marx altered Dante's words to make them fit in here. The original is '*Vien retro a me, e lascia dir le genti*' ('Follow me, and let the people talk'), in *Divina Commedia, Purgatorio,* Canto V, line 13.

Postface to the Second Edition

I must start by informing the readers of the first edition about the alterations made in the second edition. The clearer arrangement of the book will be immediately apparent. Additional notes are everywhere marked as notes to the second edition. The following are the most important points with regard to the text itself:

In Chapter 1, Section 1, the derivation of value by analysis of the equations in which every exchange-value is expressed has been carried out with greater scientific strictness; similarly, the connection between the substance of value and the determination of the magnitude of value by the labour-time socially necessary, which was only alluded to in the first edition, is now expressly emphasized. Chapter 1, Section 3 (on the form of value), has been completely revised, a task which was made necessary by the twofold presentation of it in the first edition, if by nothing else. Let me remark in passing that this twofold presentation was occasioned by my friend Dr L. Kugelmann, in Hanover. I was visiting him in the spring of 1867 when the first proof-sheets arrived from Hamburg, and he convinced me that most readers needed a supplementary, more didactic exposition of the form of value. The last section of the first chapter, 'The Fetishism of Commodities, etc.', has been altered considerably. Chapter 3, Section 1 (on the measure of values), has been carefully revised, because in the first edition this section was treated carelessly, the reader having been referred to the explanation already given in *Zur Kritik der Politischen Ökonomie*, Berlin, 1859. Chapter 7, particularly Section 2, has been re-worked to a great extent.

It would be pointless to go into all the partial textual changes, which are often purely stylistic. They occur throughout the book. Nevertheless, I find now, on revising the French translation which is appearing in Paris, that several parts of the German original stand in need of a rather thorough re-working, while other parts require rather heavy stylistic editing, and still others require the painstaking elimination of occasional slips. But there was no time for that. For I was informed only in the autumn of 1871, when in the midst of other urgent work, that the book was sold out and the printing of the second edition was to begin in January 1872.

The appreciation which *Das Kapital* rapidly gained in wide circles of the German working class is the best reward for my labours. A man who in economic matters represents the bourgeois standpoint, the Viennese manufacturer Herr Mayer, in a pamphlet published during the Franco-German War,* aptly expounded the idea that the great capacity for theory, which used to be considered a hereditary German attribute, had almost completely disappeared amongst the so-called educated classes in Germany, but that amongst the working class, on the contrary, it was enjoying a revival.

Political economy remains a foreign science in Germany, up to this very moment. In his *Geschichtliche Darstellung des Handels, der Gewerbe, usw.*,† especially in the first two volumes, published in 1830, Gustav von Gülich has already examined, for the most part, the historical circumstances that prevented the development of the capitalist mode of production in Germany, and consequently the construction there of modern bourgeois society. Thus the living soil from which political economy springs was absent. It had to be imported from England and France as a ready-made article; its German professors always remained pupils. The theoretical expression of an alien reality turned in their hands into a collection of dogmas, interpreted by them in the sense of the petty-bourgeois world surrounding them, and therefore misinterpreted. The feeling of scientific impotence, a feeling which could not entirely be suppressed, and the uneasy awareness that they had to master an area in fact entirely foreign to them, was only imperfectly concealed beneath a parade of literary and historical erudition, or by an admixture of extraneous material borrowed from the so-called *kameral* sciences,‡ a medley of smatterings through whose pur-

---

† *Historical Description of Commerce, Industry, etc.*, 5 vols., Jena, 1830–45.

‡ *Kameralwissenschaft*, or Cameralism, was the German version of Mercantilism. It tended to see political economy in narrow terms as a matter of finance and administration, since it arose as a set of ideas as to how the rulers of German princely states could use their revenues to promote the state's well being. Notable Cameralists were von Hörnigkh in the seventeenth and Justi in the eighteenth century.

gatory the hopeful candidate for the German bureaucracy has to pass.

Since 1848 capitalist production has developed rapidly in Germany, and at the present time it is in the full bloom of speculation and swindling. But fate is still unpropitious to our professional economists. At the time when they were able to deal with political economy in an unprejudiced way, modern economic conditions were absent from the reality of Germany. And as soon as these conditions did come into existence, it was under circumstances that no longer permitted their impartial investigation within the bounds of the bourgeois horizon. In so far as political economy is bourgeois, i.e. in so far as it views the capitalist order as the absolute and ultimate form of social production, instead of as a historically transient stage of development, it can only remain a science while the class struggle remains latent or manifests itself only in isolated and sporadic phenomena.

Let us take England. Its classical political economy belongs to a period in which the class struggle was as yet undeveloped. Its last great representative, Ricardo, ultimately (and consciously) made the antagonism of class interests, of wages and profits, of profits and rent, the starting-point of his investigations, naïvely taking this antagonism for a social law of nature. But with this contribution the bourgeois science of economics had reached the limits beyond which it could not pass. Already in Ricardo's lifetime, and in opposition to him, it was met by criticism in the person of Sismondi.[1]

The succeeding period, from 1820 to 1830, was notable in England for the lively scientific activity which took place in the field of political economy. It was the period of both the vulgarizing and the extending of Ricardo's theory, and of the contest of that theory with the old school. Splendid tournaments were held. What was achieved at that time is little known on the European Continent, because the polemic is for the most part scattered over articles in reviews, *pièces d'occasion* and pamphlets. The unprejudiced character of this polemic – although Ricardo's theory already serves, in exceptional cases, as a weapon with which to attack the bourgeois economic system – is explained by the circumstances of the time. On the one hand, large-scale industry itself was only just emerging from its childhood, as is shown by the fact that the periodic cycle of its modern life opens for the first time with the crisis of 1825. On the other hand, the class struggle between capital and labour was forced into the background, politically by the discord between the governments and the feudal aristocracy gathered around the Holy Alliance, assembled in one camp, and the mass of the people, led by the bourgeoisie, in the other camp, and economically by the quarrel between industrial capital and aristocratic landed property. This latter quarrel was concealed in France by the antagonism between small-scale, fragmented property and big landownership, but in England it broke out openly after the passing of the Corn Laws. The literature of political economy in England at this time calls to mind the economic 'storm and stress period' which in France followed the death of Dr Quesnay,* but only as an Indian summer reminds us of spring. With the year 1830 there came the crisis which was to be decisive, once and for all.

---

[1] See my work *Zur Kritik der Politischen Ökonomie*, p. 39 [English translation, p. 61].

In France and England the bourgeoisie had conquered political power. From that time on, the class struggle took on more and more explicit and threatening forms, both in practice and in theory. It sounded the knell of scientific bourgeois economics. It was thenceforth no longer a question whether this or that theorem was true, but whether it was useful to capital or harmful, expedient or inexpedient, in accordance with police regulations or contrary to them. In place of disinterested inquirers there stepped hired prize-fighters; in place of genuine scientific research, the bad conscience and evil intent of apologetics. Still, even the importunate pamphlets with which the Anti-Corn Law League, led by the manufacturers Cobden and Bright, deluged the world offer a historical interest, if no scientific one, on account of their polemic against the landed aristocracy. But since then the free-trade legislation inaugurated by Sir Robert Peel has deprived vulgar economics even of this, its last sting.

The Continental revolution of 1848 also had its reaction in

*Dr Quesnay died in 1774. His death was immediately followed by Turgot's attempt to put Physiocratic ideas into practice, while he was Louis XVI's Controller-General (1774–6). His fall in 1776 opened a period of political and economic crisis which culminated in the French Revolution. It is this which Marx has in mind, rather than the (somewhat exiguous) theoretical writings of the period after 1774.

England. Men who still claimed some scientific standing and aspired to be something more than mere sophists and sycophants of the ruling classes tried to harmonize the political economy of capital with the claims, no longer to be ignored, of the proletariat. Hence a shallow syncretism, of which John Stuart Mill is the best representative. This is a declaration of bankruptcy by 'bourgeois' economics, an event already illuminated in a masterly manner by the great Russian scholar and critic N. Chernyshevsky, in his *Outlines of Political Economy According to Mill.*

In Germany, therefore, the capitalist mode of production came to maturity after its antagonistic character had already been revealed, with much sound and fury, by the historical struggles which took place in France and England. Moreover, the German proletariat had in the meantime already attained a far clearer theoretical awareness than the German bourgeoisie. Thus, at the very moment when a bourgeois science of political economy at last seemed possible in Germany, it had in reality again become impossible.

Under these circumstances its spokesmen divided into two groups. The one set, prudent, practical business folk, flocked to the banner of Bastiat, the most superficial and therefore the most successful representative of apologetic vulgar economics; the other set, proud of the professorial dignity of their science, followed John Stuart Mill in his attempt to reconcile the irreconcilable. Just as in the classical period of bourgeois economics, so also in the period of its decline, the Germans remained mere pupils, imitators and followers, petty retailers and hawkers in the service of the great foreign wholesale concern.

The peculiar historical development of German society therefore excluded any original development of 'bourgeois' economics there, but did not exclude its critique. In so far as such a critique represents a class, it can only represent the class whose historical task is the overthrow of the capitalist mode of production and the final abolition of all classes – the proletariat.

The learned and unlearned spokesmen of the German bourgeoisie tried at first to kill *Das Kapital* with silence, a technique which had succeeded with my earlier writings. As soon as they found that these tactics no longer fitted the conditions of the time, they wrote prescriptions 'for tranquillizing the bourgeois mind', on the pretext of criticizing my book. But they found in the workers' press – see for example Joseph Dietzgen's articles in the

*Volksstaat** – champions stronger than themselves, to whom they still owe a reply even now.[2]

An excellent Russian translation of *Capital* appeared in the spring of 1872 in St Petersburg. The edition of 3,000 copies is already nearly exhausted. As early as 1871, N. Sieber, Professor of Political Economy in the University of Kiev, in his work *David Ricardo's Theory of Value and of Capital*, referred to my theory of value, money and capital as in its fundamentals a necessary sequel to the teaching of Smith and Ricardo. What astonishes a Western European when he reads this solid piece of work is the author's consistent and firm grasp of the purely theoretical position.

That the method employed in *Capital* has been little understood is shown by the various mutually contradictory conceptions that have been formed of it.

Thus the Paris *Revue Positiviste*† reproaches me for, on the one hand, treating economics metaphysically, and, on the other hand – imagine this! – confining myself merely to the critical analysis of the actual facts, instead of writing recipes (Comtist ones?) for the cook-shops of the future. Professor Sieber has already given the answer to the reproach about metaphysics: 'In so far as it deals

[2] The mealy-mouthed babblers of German vulgar economics grumbled about the style of my book. No one can feel the literary shortcomings of *Capital* more strongly than I myself. Yet I will quote in this connection one English and one Russian notice, for the benefit and enjoyment of these gentlemen and their public. The *Saturday Review*, an entirely hostile journal, said in its notice of the first edition: 'The presentation of the subject invests the driest economic questions with a certain peculiar charm.' The *St Petersburg Journal* (*Sankt-Peterburgskye Vyedomosty*), in its issue of 20 April 1872, says: 'The presentation of the subject, with the exception of one or two excessively specialized parts, is distinguished by its comprehensibility to the general reader, its clearness, and, in spite of the high scientific level of the questions discussed, by an unusual liveliness. In this respect the author in no way resembles . . . the majority of German scholars, who . . . write their books in a language so dry and obscure that the heads of ordinary mortals are cracked by it.'

---

*Dietzgen's articles on *Capital* actually appeared in Nos. 31, 34, 35 and 36 of the *Demokratisches Wochenblatt* in 1868. After the founding congress of the German Social Democratic Workers' Party in 1869 the paper was made its official organ, and renamed *Der Volksstaat*.

†*La Philosophie Positive. Revue* was the journal of the followers of Auguste Comte. It appeared in Paris between 1867 and 1883, under the editorship of E. Littré.

with actual theory, the method of Marx is the deductive method of the whole English school, a school whose failings and virtues are common to the best theoretical economists.' Mr M. Block – in *Les Théoriciens du socialisme en Allemagne. Extrait du Journal des économistes, Juillet et Août 1872* – makes the discovery that my method is analytic, and says: 'With this work, M. Marx can be ranged among the most eminent analytical thinkers.' The German reviewers, of course, cry out against my 'Hegelian sophistry'. The *European Messenger* (*Vyestnik Evropy*) of St Petersburg, in an article dealing exclusively with the method of *Capital* (May 1872 issue, pp. 427–36), finds my method of inquiry severely realistic, but my method of presentation, unfortunately, German-dialectical. It says: 'At first sight, if the judgement is made on the basis of the external form of the presentation, Marx is the most idealist of philosophers, and indeed in the German, i.e. the bad sense of the word. But in point of fact he is infinitely more realistic than all his predecessors in the business of economic criticism . . . He can in no sense be called an idealist.' I cannot answer the writer of this review* in any better way than by quoting a few extracts from his own criticism, which may, apart from this, interest some of my readers for whom the Russian original is inaccessible.

After a quotation from the preface to my *Zur Kritik der Politischen Ökonomie*, Berlin, 1850, p. iv–vii,† where I have discussed the materialist basis of my method, the reviewer goes on: 'The one thing which is important for Marx is to find the law of the phenomena with whose investigation he is concerned; and it is not only the law which governs these phenomena, in so far as they have a definite form and mutual connection within a given historical period, that is important to him. Of still greater importance to him is the law of their variation, of their development, i.e. of their transition from one form into another, from one series of connections into a different one. Once he has discovered this law, he investigates in detail the effects with which it manifests itself in social life . . . Consequently, Marx only concerns himself with one thing: to show, by an exact scientific investigation, the necessity of successive determinate orders of social relations, and to establish, as impeccably as possible, the facts from which he starts out and on which he depends. For this it is quite enough, if he proves, at the same time, both the necessity of the present order of things, and the necessity of another order into which the first must inevitably pass over; and it is a matter of indifference whether men believe or do not believe it, whether they are conscious of it or not. Marx treats the social movement as a process of natural history, governed by laws not only independent of human will, consciousness and intelligence, but rather, on the contrary, determining that will, consciousness and intelligence . . . If the conscious element plays such a subordinate part in the history of civilization, it is self-evident that a critique whose object is civilization itself can, less than anything else, have for its basis any form or any result of consciousness. This means that it is not the idea but only its external manifestation which can serve as the starting-point. A critique of this kind will confine itself to the confrontation and comparison of a fact, not with ideas, but with another fact. The only things of importance for this inquiry are that the facts be investigated as accurately as possible, and that they actually form different aspects of development *vis-à-vis* each other. But most important of all is the precise analysis of the series of successions, of the sequences and links within which the different stages of development present themselves. It will be said, against this, that the general laws of economic life are one and the same, no matter whether they are applied to the present or the past. But this is exactly what Marx denies. According to him, such abstract laws do not exist . . . On the contrary, in his opinion, every historical period possesses its own laws . . . As soon as life has passed through a given period of development, and is passing over from one given stage to another, it begins to be subject also to other laws. In short, economic life offers us a phenomenon analogous to the history of evolution in other branches of biology . . . The old economists misunderstood the nature of economic laws when they likened them to the laws of physics and chemistry. A more thorough analysis of the phenomena shows that social organisms differ among themselves as fundamentally as plants or animals. Indeed, one and the same phenomenon falls under quite different laws in consequence of the different general structure of these organisms, the variations of their individual organs, and the different conditions in which those organs function. Marx denies, for example, that the law of population is the same at all times and in all places. He asserts, on the contrary, that every stage of development has its own law of population ... With the varying degrees of development of productive power, social conditions and the laws governing them vary too. While Marx sets himself the task of following and explaining the capitalist economic order from this point of view, he is only formulating, in a strictly scientific manner, the aim that every accurate investigation into economic life must have ... The scientific value of such an inquiry lies in the illumination of the special laws that regulate the origin, existence, development and death of a given social organism and its replacement by another, higher one. And in fact this is the value of Marx's book.'

---

*I. I. Kaufman (1848–1916), Russian economist, Professor of Political Economy at the University of St Petersburg, and author of numerous works on money and credit.

†English translation, pp. 19–23.

Here the reviewer pictures what he takes to be my own actual method, in a striking and, as far as concerns my own application of it, generous way. But what else is he depicting but the dialectical method?

Of course the method of presentation must differ in form from that of inquiry. The latter has to appropriate the material in detail, to analyse its different forms of development and to track down their inner connection. Only after this work has been done can the real movement be appropriately presented. If this is done successfully, if the life of the subject-matter is now reflected back in the ideas, then it may appear as if we have before us an *a priori* construction.

My dialectical method is, in its foundations, not only different from the Hegelian, but exactly opposite to it. For Hegel, the process of thinking, which he even transforms into an independent subject, under the name of 'the Idea', is the creator of the real world, and the real world is only the external appearance of the idea. With me the reverse is true: the ideal is nothing but the material world reflected in the mind of man, and translated into forms of thought.

I criticized the mystificatory side of the Hegelian dialectic nearly thirty years ago, at a time when it was still the fashion. But just when I was working at the first volume of *Capital*, the ill-humoured, arrogant and mediocre epigones who now talk large in educated German circles began to take pleasure in treating Hegel in the same way as the good Moses Mendelssohn treated Spinoza in Lessing's time, namely as a 'dead dog'.* I therefore openly avowed myself the pupil of that mighty thinker, and even, here and there in the chapter on the theory of value, coquetted with the mode of expression peculiar to him. The mystification which the dialectic suffers in Hegel's hands by no means prevents him from being the first to present its general forms of motion in a comprehensive and conscious manner. With him it is standing on its head. It must be inverted, in order to discover the rational kernel within the mystical shell.

---

*Moses Mendelssohn (1729–86) was a philosopher who popularized the ideas of the Enlightenment in Germany, and a friend of Lessing. Marx refers here to Mendelssohn's controversy with Jacobi over the alleged Spinozism of

In its mystified form, the dialectic became the fashion in Germany, because it seemed to transfigure and glorify what exists. In its rational form it is a scandal and an abomination to the bourgeoisie and its doctrinaire spokesmen, because it includes in its positive understanding of what exists a simultaneous recognition of its negation, its inevitable destruction; because it regards every historically developed form as being in a fluid state, in motion, and therefore grasps its transient aspect as well; and because it does not let itself be impressed by anything, being in its very essence critical and revolutionary.

The fact that the movement of capitalist society is full of contradictions impresses itself most strikingly on the practical bourgeois in the changes of the periodic cycle through which modern industry passes, the summit of which is the general crisis. That crisis is once again approaching, although as yet it is only in its preliminary stages, and by the universality of its field of action and the intensity of its impact it will drum dialectics even into the heads of the upstarts in charge of the new Holy Prussian-German Empire.

Karl Marx

London, 24 January 1873

Lessing. In the pamphlet 'Moses Mendelssohn to the Friends of Lessing' (1786), he defends the latter against this 'accusation' and the related one of atheism.

Preface to the French Edition

To citizen Maurice La Châtre

Dear Citizen,

I applaud your idea of publishing the translation of *Capital* as a serial. In this form the book will be more accessible to the working class, a consideration which to me outweighs everything else.

That is the good side of your suggestion, but here is the reverse of the medal: the method of analysis which I have employed, and which had not previously been applied to economic subjects, makes the reading of the first chapters rather arduous, and it is to be feared that the French public, always impatient to come to a conclusion, eager to know the connection between general principles and the immediate questions that have aroused their passions, may be disheartened because they will be unable to move on at once.

That is a disadvantage I am powerless to overcome, unless it be by forewarning and forearming those readers who zealously seek the truth. There is no royal road to science, and only those who do not dread the fatiguing climb of its steep paths have a chance of gaining its luminous summits.

Believe me, dear citizen,

Your devoted,
Karl Marx

London, 18 March 1872

Postface to the French Edition

To the Reader

Mr J. Roy set himself the task of producing a version that would be as exact and even literal as possible, and has scrupulously fulfilled it. But his very scrupulousness has compelled me to modify his text, with a view to rendering it more intelligible to the reader. These alterations, introduced from day to day, as the book was published in parts, were not made with equal care and were bound to result in a lack of harmony in style.

Having once undertaken this work of revision, I was led to apply it also to the basic original text (the second German edition), to simplify some arguments, to complete others, to give additional historical or statistical material, to add critical suggestions, etc. Hence, whatever the literary defects of this French edition may be, it possesses a scientific value independent of the original and should be consulted even by readers familiar with German.

Below I give the passages in the Postface to the second German edition which treat of the development of political economy in Germany and the method employed in the present work.*

Karl Marx

London, 28 April 1875

---

* See above, pp. 95–103.

Preface to the Third Edition

Marx was not destined to get this, the third edition, ready for the press himself. The powerful thinker, to whose greatness even his opponents now make obeisance, died on 14 March 1883.

Upon me who, in Marx, lost the best, the truest friend I had – and had for forty years – the friend to whom I am more indebted than can be expressed in words – upon me now devolved the duty of attending to the publication of this third edition, as well as of the second volume, which Marx had left behind in manuscript. I must now account here to the reader for the way in which I discharged the first part of my duty.

It was Marx's original intention to re-write a great part of the text of the first volume, to formulate many theoretical points more exactly, to insert new ones, and to bring historical and statistical materials up to date. But his ailing condition and the urgent need to do the final editing of the second volume* induced him to give up this scheme. Only the most necessary alterations were to be made, only the insertions which the French edition (*Le Capital*, par Karl Marx, Paris, Lachâtre, 1873†) already contained were to be put in.

Among the books left by Marx there was a German copy which he himself had corrected here and there and provided with references to the French edition; also a French copy in which he had indicated the exact passages to be used. These alterations and additions are confined, with few exceptions, to Part Seven of the book, entitled 'The Process of Accumulation of Capital'. Here the previous text followed the original draft more closely than elsewhere, while the preceding sections had been gone over more thoroughly. The style was therefore more vivacious, more of a single cast, but also more careless, studded with Anglicisms and in parts unclear; there were gaps here and there in the presentation of arguments, some important particulars being merely alluded to.

---

*See above, p. 93, first note.

†The French edition appeared in instalments between 1872 and 1875.

With regard to the style, Marx had himself thoroughly revised several sub-sections and had thereby indicated to me here, as well as in numerous oral suggestions, the length to which I could go in eliminating English technical terms and other Anglicisms. Marx would in any event have gone over the additions and supplementary texts and have replaced the smooth French with his own terse German; I had to be satisfied, when transferring them, with bringing them into maximum harmony with the original text.

Thus not a single word was changed in this third edition without my firm conviction that the author would have altered it himself. It would never occur to me to introduce into *Capital* the current jargon in which German economists are wont to express themselves – that gibberish in which, for instance, one who has others give him their labour for cash is called a labour-*giver* [*Arbeitgeber*] and one whose labour is taken away from him for wages is called a labour-*taker* [*Arbeitnehmer*]. In French, too, the word '*travail*' is used in every-day life in the sense of 'occupation'. But the French would rightly consider any economist crazy should he call the capitalist a *donneur de travail* (labour-giver) or the worker a *receveur de travail* (labour-taker).

Nor have I taken the liberty of converting the English coins and money, weights and measures used throughout the text into their new German equivalents. When the first edition appeared there were as many kinds of weights and measures in Germany as there are days in the year. Apart from this, there were two kinds of mark (the *Reichsmark* only existed at the time in the imagination of Soetbeer, who had invented it in the late thirties), two kinds of guilder, and at least three kinds of thaler, including one called the *neues Zweidrittel.** In the natural sciences the metric system prevailed, in the world market – English weights and measures. Under such circumstances, English units of measurement were quite natural for a book which had to take its factual proofs almost exclusively from the conditions prevailing in English industry. The last-named reason is decisive even today, especially as the corresponding conditions in the world market have hardly

* 'New two-thirds': a silver coin worth $\frac{2}{3}$ of a thaler, which circulated in a number of German principalities between the seventeenth and the nineteenth centuries.

changed and English weights and measures almost entirely predominate, particularly in the key industries, iron and cotton.

In conclusion, a few words on Marx's manner of quoting, which is so little understood. When they are pure statements of fact or descriptions, the quotations, from the English Blue Books, for example, serve of course as simple documentary proof. But this is not so when the theoretical views of other economists are cited. Here the quotation is intended merely to state where, when and by whom an economic idea conceived in the course of development was first clearly enunciated. Here the only consideration is that the economic conception in question must be of some significance to the history of the science, that it is the more or less adequate theoretical expression of the economic situation of its time. But whether this conception still possesses any absolute or relative validity from the standpoint of the author or whether it has already become wholly past history is quite immaterial. Hence these quotations are only a running commentary to the text, a commentary borrowed from the history of economic science. They establish the dates and originators of certain of the more important advances in economic theory. And that was a very necessary thing in a science whose historians have so far distinguished themselves only by the tendentious ignorance characteristic of place-hunters. It will now be understood why Marx, in consonance with the Postface to the second edition, only had occasion to quote German economists in very exceptional cases.

There is hope that the second volume will appear in the course of 1884.

Frederick Engels

London, 7 November 1883

Preface to the English Edition

The publication of an English version of *Das Kapital* needs no apology. On the contrary, an explanation might be expected why this English version has been delayed until now, seeing that for some years past the theories advocated in this book have been constantly referred to, attacked and defended, interpreted and misinterpreted, in the periodical press and the current literature of both England and America.

When, soon after the author's death in 1883, it became evident that an English edition of the work was really required, Mr Samuel Moore, for many years a friend of Marx and of the present writer, and than whom, perhaps, no one is more conversant with the book itself, consented to undertake the translation which the literary executors of Marx were anxious to lay before the public. It was understood that I should compare the MS. with the original work, and suggest such alterations as I might deem advisable. When, by and by, it was found that Mr Moore's professional occupations prevented him from finishing the translation as quickly as we all desired, we gladly accepted Dr Aveling's offer to undertake a portion of the work; at the same time Mrs Aveling, Marx's youngest daughter, offered to check the quotations and to restore the original text of the numerous passages taken from English authors and Blue Books and translated by Marx into German. This has been done throughout, with but a few unavoidable exceptions.

The following portions of the book have been translated by Dr Aveling: (1) Chapters 10 ('The Working Day') and 11 ('Rate and Mass of Surplus-Value'); (2) Part Six ('Wages', comprising Chapters 19 to 22); (3) from Chapter 24, Section 4 ('Circumstances which' etc.) to the end of the book, comprising the latter part of Chapter 24, Chapter 25, and the whole of Part Eight (Chapters 26 to 33); (4) the two author's Prefaces.* All the rest of the book has been done by Mr Moore. While, thus, each of the translators is responsible for his share of the work only, I bear a joint responsibility for the whole.

The third German edition, which has been made the basis of our work throughout, was prepared by me, in 1883, with the assistance of notes left by the author, indicating the passages of the second edition to be replaced by designated passages from the French text published in 1873.[1] The alterations thus effected in the text of the second edition generally coincided with changes prescribed by Marx in a set of MS. instructions for an English translation that was planned, about ten years ago, in America, but abandoned chiefly for want of a fit and proper translator. This MS. was placed at our disposal by our old friend Mr F. A. Sorge of Hoboken, N.J. It designates some further interpolations from the French edition; but, being so many years older than the final instructions for the third edition, I did not consider myself at liberty to make use of it otherwise than sparingly, and chiefly in cases where it helped us over difficulties. In the same way, the French text has been referred to in most of the difficult passages, as an indicator of what the author himself was prepared to sacrifice wherever something of the full import of the original had to be sacrificed in the rendering.

[1] *Le Capital, par Karl Marx. Traduction de M. J. Roy, entièrement revisée par l'auteur*, Paris, Lachâtre. This translation, especially in the latter part of the book, contains considerable alterations in and additions to the text of the second German edition.

---

* For the English edition of *Capital*, Engels changed Marx's earlier division of the book into chapters and parts, making the three sections of what was Chapter 4 and the seven sections of what was Chapter 24 into separate chapters. For reasons of convenience to English readers, we have held to Engels's arrangement. We have also followed Engels in presenting the chapters on 'So-called Primitive Accumulation' as a separate Part VIII, which is certainly justifiable in view of its special subject matter. The following table shows the relation between parts and chapters in English and German editions:

	German	*English*
Chapters	1–3	1–3
	4	4–6
	5–23	7–25
	24	26–32
	25	33
Parts	One–Six	One–Six
	Seven	Seven–Eight

There is, however, one difficulty we could not spare the reader: the use of certain terms in a sense different from what they have, not only in common life, but in ordinary political economy. But this was unavoidable. Every new aspect of a science involves a revolution in the technical terms of that science. This is best shown by chemistry, where the whole of the terminology is radically changed about once in twenty years, and where you will hardly find a single organic compound that has not gone through a whole series of different names. Political economy has generally been content to take, just as they were, the terms of commercial and industrial life, and to operate with them, entirely failing to see that by so doing it confined itself within the narrow circle of ideas expressed by those terms. Thus, though perfectly aware that both profits and rent are but sub-divisions, fragments of that unpaid part of the product which the labourer has to supply to his employer (its first appropriator, though not its ultimate exclusive owner), yet even classical political economy never went beyond the received notions of profits and rents, never examined this unpaid part of the product (called by Marx surplus product) in its integrity as a whole, and therefore never arrived at a clear comprehension, either of its origin and nature, or of the laws that regulate the subsequent distribution of its value. Similarly all industry, not agricultural or handicraft, is indiscriminately comprised in the term of manufacture, and thereby the distinction is obliterated between two great and essentially different periods of economic history: the period of manufacture proper, based on the division of manual labour, and the period of modern industry based on machinery. It is, however, self-evident that a theory which views modern capitalist production as a mere passing stage in the economic history of mankind, must make use of terms different from those habitual to writers who look upon that form of production as imperishable and final.

A word respecting the author's method of quoting may not be out of place. In the majority of cases, the quotations serve, in the usual way, as documentary evidence in support of assertions made in the text. But in many instances, passages from economic writers are quoted in order to indicate when, where and by whom a certain proposition was for the first time clearly enunciated. This is done in cases where the proposition quoted is of importance as being a more or less adequate expression of the conditions of social production and exchange prevalent at the time, and quite irrespective of Marx's recognition, or otherwise, of its general validity. These quotations, therefore, supplement the text by a running commentary taken from the history of the science.

Our translation comprises the first book of the work only. But this first book is in a great measure a whole in itself, and has for twenty years ranked as an independent work. The second book, edited in German by me in 1885, is decidedly incomplete without the third, which cannot be published before the end of 1887. When Book III has been brought out in the original German, it will then be soon enough to think about preparing an English edition of both.

Capital is often called, on the Continent, 'the Bible of the working class'. That the conclusions arrived at in this work are daily more and more becoming the fundamental principles of the great working-class movement, not only in Germany and Switzerland, but in France, in Holland and Belgium, in America, and even in Italy and Spain, that everywhere the working class more and more recognizes, in these conclusions, the most adequate expression of its condition and of its aspirations, nobody acquainted with that movement will deny. And in England, too, the theories of Marx, even at this moment, exercise a powerful influence upon the socialist movement which is spreading in the ranks of 'cultured' people no less than in those of the working class. But that is not all. The time is rapidly approaching when a thorough examination of England's economic position will impose itself as an irresistible national necessity. The working of the industrial system of this country, impossible without a constant and rapid extension of production, and therefore of markets, is coming to a dead stop. Free-trade has exhausted its resources; even Manchester doubts this its *quondam* economic gospel.[2] Foreign industry, rapidly developing, stares English production in the face everywhere, not only in protected, but also in neutral markets, and even on this side of the Channel. While the productive power increases in a geometric ratio, the extension of markets proceeds at best in an arithmetic one. The decennial cycle of stagnation, prosperity, overproduction and crisis, ever recurrent from 1825 to 1867, seems indeed to have run its course; but only to land us in the slough of despond of a permanent and chronic depression. The sighed-for period of prosperity will not come; as often as we seem to perceive its heralding symptoms, so often do they again vanish into air. Meanwhile, each succeeding winter brings up afresh the great question, 'what to do with the unemployed'; but while the number of the unemployed keeps swelling from year to year, there is nobody to answer that question; and we can almost calculate the moment when the unemployed, losing patience, will take their own fate into their own hands. Surely, at such a moment, the voice ought to be heard of a man whose whole theory is the result of a life-long study of the economic history and condition of England, and whom that study led to the conclusion that, at least in Europe, England is the only country where the inevitable social revolution might be effected entirely by peaceful and legal means. He certainly never forgot to add that he hardly expected the English ruling classes to submit, without a 'pro-slavery rebellion',* to this peaceful and legal revolution.

---

[2] 'At the quarterly meeting of the Manchester Chamber of Commerce, held this afternoon, a warm discussion took place on the subject of Free-trade. A resolution was moved to the effect that "having waited in vain forty years for other nations to follow the Free-trade example of England, this Chamber thinks the time has now arrived to reconsider that position". The resolution was rejected by a majority of one only, the figures being 21 for, and 22 against' (*Evening Standard*, 1 November 1886).

Frederick Engels

5 November 1886

---

*This is Marx's and Engels' usual description of the American Civil War of 1861 to 1865, which was set off by the revolt of the slave-owners of the Southern states.

Preface to the Fourth Edition

The fourth edition required that I should establish in final form, as nearly as possible, both text and footnotes. The following brief explanation will show how I have fulfilled this task.

After again comparing the French edition and Marx's manuscript remarks I have made some further additions to the German text from that translation. They will be found on p. 212, pp. 624–6, pp. 730–4, pp. 777–80 and on p. 783 in note 13.* I have also followed the example of the French and English editions by putting the long footnote on the miners into the text (pp. 626–34). Other small alterations are of a purely technical nature.

Further, I have added a few more explanatory notes, especially where changed historical conditions seemed to demand this. All these additional notes are enclosed in square brackets and marked either with my initials or 'D.H.'.†

In the meantime, a complete revision of the numerous quotations had been made necessary by the publication of the English edition. For this edition Marx's youngest daughter, Eleanor, undertook to compare all the quotations with their originals, so that those taken from English sources, which constitute the vast majority, are given there not as re-translations from the German but in the original English form. In preparing the fourth edition it was therefore incumbent upon me to consult this text. The comparison revealed various small inaccuracies: page numbers wrongly indicated, owing partly to mistakes in copying from note-books, and partly to the accumulated misprints of three editions; misplaced quotation or omission marks, which cannot be avoided when a mass of quotations is copied from note-book extracts; here and there some rather unhappy translation of a word; particular passages quoted from the old Paris note-books of 1843–5, when Marx did not know English and was reading English economists in French translations, so that the double translation yielded a slightly different shade of meaning, as in the case of Steuart, Ure, etc., where the English text had now to be used – and other similar instances of trifling inaccuracy or negligence. But anyone who compares the fourth edition with the previous ones can convince himself that all this laborious process of emendation has not produced the smallest change in the book worth speaking of. There was only one quotation which could not be traced – the one from Richard Jones (p. 746, note 35). Marx probably slipped up when writing down the title of the book.* All the other quotations retain their cogency in full, or have had their cogency enhanced by being put into their present exact form.

---

*The page numbers in the present edition have been inserted in place of Engels' references to the third and fourth German editions.

†*Der Herausgeber*, i.e. the editor. In this edition all of Engels' additions are integrated into the text but indicated as such.

Here, however, I am obliged to revert to an old story.

I know of only one case in which the accuracy of a quotation given by Marx has been called in question. But as the issue dragged on beyond his lifetime I cannot well ignore it here.

On 7 March 1872 there appeared in the Berlin *Concordia*, the organ of the Association of German Manufacturers, an anonymous article entitled 'How Karl Marx Quotes'. It was asserted there, with an excessive display of moral indignation and unparliamentary language, that the quotation from Gladstone's Budget Speech of 16 April 1863 (in the Inaugural Address of the International Working Men's Association, 1864,† and repeated in *Capital*, Vol. 1, pp. 805–6) had been falsified; that not a single word of the sentence: 'this intoxicating augmentation of wealth and power ... is ... entirely confined to classes of property' was to be found in the (semi-official) stenographic report in *Hansard*. 'But this sentence is nowhere to be found in Gladstone's speech. Exactly the opposite is stated there.' (In bold type): '**THIS SENTENCE, BOTH IN FORM AND SUBSTANCE, IS A LIE INSERTED BY MARX.**'

Marx, to whom this issue of *Concordia* was sent the following May, answered the anonymous author in the *Volksstaat* of 1

---

*This quotation was in fact later successfully traced. Cf. below, p. 746, last note.

† See Karl Marx, *The First International and After*, Pelican Marx Library, 1974, p. 75.

June. As he could not recall which newspaper report he had used for the quotation, he limited himself to citing, first the equivalent quotation from two English publications, and then the report in *The Times*, according to which Gladstone says:

'That is the state of the case as regards the wealth of this country. I must say for one, I should look almost with apprehension and pain upon this intoxicating augmentation of wealth and power, if it were my belief that it was confined to classes who are in easy circumstances. This takes no cognizance at all of the condition of the labouring population. The augmentation I have described and which is founded, I think, upon accurate returns, is an augmentation entirely confined to classes possessed of property.'

Thus Gladstone says here that he would be sorry if this were so, but it *is* so: this intoxicating augmentation of wealth and power *is* entirely confined to classes of property. And, as for the semi-official *Hansard*, Marx goes on to say: 'In the version he manipulated afterwards, Mr Gladstone was astute enough to obliterate this passage, which, coming from an English Chancellor of the Exchequer, was certainly compromising. This, by the way, is a traditional custom in the English parliament, and not an invention got up by little Lasker against Bebel.'*

The anonymous writer gets angrier and angrier. In his rejoinder, in the *Concordia* of 4 July, he sweeps aside second-hand sources and demurely suggests that it is the 'custom' to quote parliamentary speeches from the stenographic report; adding, however, that the report in *The Times* (which includes the 'falsified' sentence) and the report in *Hansard* (which omits it) are 'substantially in complete agreement', and also that the report in *The Times* contains 'the exact opposite to that notorious passage in the *Inaugural Address*'. The fellow carefully conceals the fact that the report in *The Times* explicitly includes that self-same 'notorious passage', side by side with its alleged 'opposite'. Despite all this, however, the anonymous writer feels that he is stuck fast and that he can only save himself by some new dodge. Thus, although his article bristles, as we have just shown, with 'impudent mendacity' and is

---

*In the *Reichstag* sitting of 8 November 1871 the National Liberal deputy Lasker declared in the course of a speech against the Social Democrat Bebel that if the German workers tried to follow the example of the Paris Commune 'the honest, propertied citizens would beat them to death with cudgels'. But in the stenographic report he had the words 'beat them to death with cudgels' replaced with 'hold them down with their own strength'. Bebel immediately revealed that this was a falsification.

interlarded with such edifying terms of abuse as 'bad faith', 'dishonesty', 'lying allegation', 'that spurious quotation', 'impudent mendacity', 'a quotation entirely falsified', 'this falsification', 'simply infamous', etc., he finds it necessary to divert the issue to another domain, and therefore promises 'to explain in a second article the meaning which we' (the non-mendacious anonymous one) 'attribute to the content of Gladstone's words'. As if his particular opinion, unauthoritative as it is, had anything whatever to do with the matter! This second article was printed in the *Concordia* of 11 July.

Marx replied again in the *Volksstaat* of 7 August, now giving in addition the reports of the passage in question from the *Morning Star* and *Morning Advertiser* of 17 April 1863. According to both reports, Gladstone said that he would look with apprehension, etc. upon this intoxicating augmentation of wealth and power if he believed it to be confined to 'classes in easy circumstances'. But this augmentation *was* in fact, he said, 'entirely confined to classes possessed of property'. So these reports too reproduced word for word the sentence alleged to have been 'lyingly inserted'. Marx further established once more, by comparing the texts in *The Times* and in *Hansard*, that this sentence, which three newspaper reports of identical content, appearing independently of one another the next morning, proved to have been really uttered, was missing from the *Hansard* report, revised according to the familiar 'custom', and that Gladstone, to use Marx's words, 'had afterwards conjured it away'. In conclusion Marx stated that he had no time to enter into any further discussions with the anonymous one. The latter also seems to have had enough; at any rate Marx received no further issues of *Concordia*.

With this the matter appeared to be dead and buried. True, once or twice later on there reached us, from persons in touch with the University of Cambridge, mysterious rumours of an unspeakable literary crime which Marx was supposed to have committed in *Capital*; but despite all investigation nothing more definite could be learned. Then, on 29 November 1883, eight months after Marx's death, there appeared in *The Times* a letter headed Trinity College, Cambridge, and signed Sedley Taylor, in which this little man, who dabbles in the mildest sort of co-operative activities,* seized upon some chance pretext or other to

---

*Sedley Taylor (1834–1920), Fellow of Trinity College, Cambridge, and author of a book entitled *Profit Sharing between Capital and Labour* (1884).

enlighten us at last, not only about those vague Cambridge rumours, but also about the anonymous fellow in the *Concordia.*

'What appears extremely singular,' says the little man from Trinity College, 'is that it was reserved for *Professor Brentano* (then of the University of Breslau, now of that of Strassburg) to expose . . . the bad faith which had manifestly dictated the citation made from Mr Gladstone's speech in the [Inaugural] Address. Herr Karl Marx, who . . . attempted to defend the citation, had the hardihood, in the deadly shifts to which Brentano's masterly conduct of the attack speedily reduced him, to assert that Mr Gladstone had "manipulated" the report of his speech in *The Times* of 17 April 1863, before it appeared in *Hansard*, in order to "obliterate" a passage which "was certainly compromising" for an English Chancellor of the Exchequer. On Brentano's showing, by a detailed comparison of texts, that the reports of *The Times* and of *Hansard* agreed in utterly excluding the meaning which craftily isolated quotation had put upon Mr Gladstone's words, Marx withdrew from further controversy under the plea of "want of time".'

So that was at the bottom of the whole business! And thus was the anonymous campaign of Herr Brentano* in the *Concordia* gloriously reflected in the imagination of the producers' co-operatives of Cambridge. There he stood, sword in hand, and thus he battled, in his 'masterly conduct of the attack', this St George of the Association of German Manufacturers, while the infernal dragon Marx, 'in deadly shifts', 'speedily' breathed his last at his feet.

A battle-scene worthy of Ariosto! But the whole thing only served to conceal the further dodges of our St George. Here there is no longer talk of 'lying insertion' or 'falsification', but of 'craftily isolated quotation'. The whole issue was shifted, and St George and his Cambridge shield-bearer were very well aware why they had done this.

Eleanor Marx replied in the monthly journal *To-day* (February 1884), as *The Times* refused to publish her letter. She once more focused the debate on the sole question at issue: had Marx 'lyingly inserted' that sentence or not? To this Mr Sedley Taylor answered that 'the question whether a particular sentence did or did not occur in Mr Gladstone's speech' had been, in his opinion, 'of very subordinate importance' in the Brentano–Marx controversy, 'compared to the issue whether the quotation in dispute was made with the intention of conveying, or of perverting Mr Gladstone's meaning'. He then admits that the report in *The Times* contained 'a verbal contrariety'; but, if the context is rightly interpreted, i.e., in the Gladstonian Liberal sense, it shows what Mr Gladstone *meant* to say (*To-day*, March 1884). The most comic point here is that our little Cambridge man now insists upon quoting the speech *not* from *Hansard*, as, according to the anonymous Brentano, it is 'customary' to do, but from the report in *The Times*, which the same Brentano had characterized as 'of necessity botched'. Naturally so, for in *Hansard* the vexatious sentence is missing.

---

*Lujo Brentano (1844–1931), 'Professorial socialist', founder of the Verein für Sozialpolitik, liberal advocate of social reform, and Professor at various German universities from 1872 until 1914.

Eleanor Marx had no difficulty (in the same issue of *To-day*) in dissolving all this argumentation into thin air. Either Mr Taylor had read the controversy of 1872, in which case he was now making not only 'lying insertions' but also 'lying' suppressions; or he had not read it and ought to remain silent. In either case it was certain that he did not dare for a moment to maintain the accusation of his friend Brentano that Marx had made a 'lying' addition. On the contrary, Marx, it now seems, had not lyingly added but suppressed an important sentence. But this same sentence is quoted on page 5 of the *Inaugural Address*, a few lines before the alleged 'lying insertion',* and as to the 'contrariety' in Gladstone's speech, is it not Marx himself who refers in *Capital* (p. 806, note 40) to 'the continual crying contradictions in Gladstone's Budget speeches of 1863 and 1864'? Only he does not venture, *à la* Sedley Taylor, to resolve them into complacent Liberal sentiments. Eleanor Marx, in concluding her reply, sums up as follows:

'Marx has not suppressed anything worth quoting, neither has he "lyingly" added anything. But he has restored, rescued from oblivion, a particular sentence of one of Mr Gladstone's speeches, a sentence which had indubitably been pronounced, but which somehow or other had found its way – out of *Hansard*.'

With that, Mr Sedley Taylor too had had enough, and the result of this whole professorial cobweb, spun out over two decades and two great countries, is that nobody has since dared to cast any other aspersion upon Marx's literary honesty; while Mr Sedley Taylor, no doubt, will after this put as little confidence in the literary war bulletins of Herr Brentano as Herr Brentano will in the papal infallibility of *Hansard.**

---

*Karl Marx, op. cit. The sentence is this: 'The average condition of the British labourer has improved to a degree we know to be extraordinary and unexampled in the history of any country or any age.'

Frederick Engels

London, 25 June 1890

---

* This was not in fact the end of this controversy. Brentano came back into the fray once again, which led Engels to publish a more comprehensive refutation of Brentano's charges, with all the documents concerned appended in pamphlet form: *Brentano Contra Marx*, reprinted in *MEW* 22.

Capital

Volume One

Part One

Commodities and Money

Chapter 1: The Commodity

I. THE TWO FACTORS OF THE COMMODITY: USE-VALUE AND VALUE (SUBSTANCE OF VALUE, MAGNITUDE OF VALUE)

The wealth of societies in which the capitalist mode of production prevails appears as an 'immense collection of commodities'[1]; the individual commodity appears as its elementary form. Our investigation therefore begins with the analysis of the commodity.

The commodity is, first of all, an external object, a thing which through its qualities satisfies human needs of whatever kind. The nature of these needs, whether they arise, for example, from the stomach, or the imagination, makes no difference.[2] Nor does it matter here how the thing satisfies man's need, whether directly as a means of subsistence, i.e. an object of consumption, or indirectly as a means of production.

Every useful thing, for example, iron, paper, etc., may be looked at from the two points of view of quality and quantity. Every useful thing is a whole composed of many properties; it can therefore be useful in various ways. The discovery of these ways and hence of the manifold uses of things is the work of history.[3] So also is the invention of socially recognized standards of measurement for the quantities of these useful objects. The diversity of the

---

1. Karl Marx, *Zur Kritik der Politischen Ökonomie*, Berlin, 1859, p. 3 [English translation, p. 27].

2. 'Desire implies want; it is the appetite of the mind, and as natural as hunger to the body ... The greatest number (of things) have their value from supplying the wants of the mind' (Nicholas Barbon, *A Discourse on Coining the New Money Lighter. In Answer to Mr Locke's Considerations etc.*, London, 1696, pp. 2, 3).

3. 'Things have an intrinsick vertue' (this is Barbon's special term for use-value) 'which in all places have the same vertue; as the loadstone to attract iron' (op. cit., p. 6). The magnet's property of attracting iron only became useful once it had led to the discovery of magnetic polarity.

measures for commodities arises in part from the diverse nature of the objects to be measured, and in part from convention.

The usefulness of a thing makes it a use-value.[4] But this usefulness does not dangle in mid-air. It is conditioned by the physical properties of the commodity, and has no existence apart from the latter. It is therefore the physical body of the commodity itself, for instance iron, corn, a diamond, which is the use-value or useful thing. This property of a commodity is independent of the amount of labour required to appropriate its useful qualities. When examining use-values, we always assume we are dealing with definite quantities, such as dozens of watches, yards of linen, or tons of iron. The use-values of commodities provide the material for a special branch of knowledge, namely the commercial knowledge of commodities.[5] Use-values are only realized [*verwirklicht*] in use or in consumption. They constitute the material content of wealth, whatever its social form may be. In the form of society to be considered here they are also the material bearers [*Träger*] of . . . exchange-value.

Exchange-value appears first of all as the quantitative relation, the proportion, in which use-values of one kind exchange for use-values of another kind.[6] This relation changes constantly with time and place. Hence exchange-value appears to be something accidental and purely relative, and consequently an intrinsic value, i.e. an exchange-value that is inseparably connected with the commodity, inherent in it, seems a contradiction in terms.[7] Let us consider the matter more closely.

[4] 'The natural worth of anything consists in its fitness to supply the necessities, or serve the conveniences of human life' (John Locke, 'Some Considerations on the Consequences of the Lowering of Interest' (1691), in *Works*, London, 1777, Vol. 2, p. 28). In English writers of the seventeenth century we still often find the word 'worth' used for use-value and 'value' for exchange-value. This is quite in accordance with the spirit of a language that likes to use a Teutonic word for the actual thing, and a Romance word for its reflection.

[5] In bourgeois society the legal fiction prevails that each person, as a buyer, has an encyclopedic knowledge of commodities.

[6] 'Value consists in the exchange relation between one thing and another, between a given amount of one product and a given amount of another' (Le Trosne, *De l'intérêt social*, in *Physiocrates*, ed. Daire, Paris, 1846, p. 889).

[7] 'Nothing can have an intrinsick value' (N. Barbon, op. cit., p. 6); or as Butler says:

> 'The value of a thing
> Is just as much as it will bring.'*

*Samuel Butler, *Hudibras*, Part 2, Canto 1, lines 465–6, 'For what is worth in any thing, but so much money as 'twill bring?'

A given commodity, a quarter of wheat for example, is exchanged for x boot-polish, y silk or z gold, etc. In short, it is exchanged for other commodities in the most diverse proportions. Therefore the wheat has many exchange-values instead of one. But x boot-polish, y silk or z gold, etc., each represent the exchange-value of one quarter of wheat. Therefore x boot-polish, y silk, z gold, etc., must, as exchange-values, be mutually replaceable or of identical magnitude. It follows from this that, firstly, the valid exchange-values of a particular commodity express something equal, and secondly, exchange-value cannot be anything other than the mode of expression, the 'form of appearance',* of a content distinguishable from it.

Let us now take two commodities, for example corn and iron. Whatever their exchange relation may be, it can always be represented by an equation in which a given quantity of corn is equated to some quantity of iron, for instance 1 quarter of corn = x cwt of iron. What does this equation signify? It signifies that a common element of identical magnitude exists in two different things, in 1 quarter of corn and similarly in x cwt of iron. Both are therefore equal to a third thing, which in itself is neither the one nor the other. Each of them, so far as it is exchange-value, must therefore be reducible to this third thing.

A simple geometrical example will illustrate this. In order to determine and compare the areas of all rectilinear figures we split them up into triangles. Then the triangle itself is reduced to an expression totally different from its visible shape: half the product of the base and the altitude. In the same way the exchange values of commodities must be reduced to a common element, of which they represent a greater or a lesser quantity.

This common element cannot be a geometrical, physical, chemical or other natural property of commodities. Such properties come into consideration only to the extent that they make the commodities useful, i.e. turn them into use-values. But clearly, the exchange relation of commodities is characterized precisely by its abstraction from their use-values. Within the exchange relation, one use-value is worth just as much as another, provided only that it is present in the appropriate quantity. Or, as old Barbon says: 'One sort of wares are as good as another, if the value be equal. There is no difference or distinction in things of equal value ...

---

* *Erscheinungsform.* This word appears in inverted commas in the original.

One hundred pounds worth of lead or iron, is of as great a value as one hundred pounds worth of silver and gold.'[8]

As use-values, commodities differ above all in quality, while as exchange-values they can only differ in quantity, and therefore do not contain an atom of use-value.

If then we disregard the use-value of commodities, only one property remains, that of being products of labour. But even the product of labour has already been transformed in our hands. If we make abstraction from its use-value, we abstract also from the material constituents and forms which make it a use-value. It is no longer a table, a house, a piece of yarn or any other useful thing. All its sensuous characteristics are extinguished. Nor is it any longer the product of the labour of the joiner, the mason or the spinner, or of any other particular kind of productive labour. With the disappearance of the useful character of the products of labour, the useful character of the kinds of labour embodied in them also disappears; this in turn entails the disappearance of the different concrete forms of labour. They can no longer be distinguished, but are all together reduced to the same kind of labour, human labour in the abstract.

Let us now look at the residue of the products of labour. There is nothing left of them in each case but the same phantom-like objectivity; they are merely congealed quantities of homogeneous human labour, i.e. of human labour-power expended without regard to the form of its expenditure. All these things now tell us is that human labour-power has been expended to produce them, human labour is accumulated in them. As crystals of this social substance, which is common to them all, they are values – commodity values [*Warenwerte*].

We have seen that when commodities are in the relation of exchange, their exchange-value manifests itself as something totally independent of their use-value. But if we abstract from their use-value, there remains their value, as it has just been defined. The common factor in the exchange relation, or in the exchange-value of the commodity, is therefore its value. The progress of the investigation will lead us back to exchange-value as the necessary mode of expression, or form of appearance, of value. For the present, however, we must consider the nature of value independently of its form of appearance [*Erscheinungs form*].

---

[8] N. Barbon, op. cit., pp. 53 and 7.

A use-value, or useful article, therefore, has value only because abstract human labour is objectified [*vergegenständlicht*] or materialized in it. How, then, is the magnitude of this value to be measured? By means of the quantity of the 'value-forming substance', the labour, contained in the article. This quantity is measured by its duration, and the labour-time is itself measured on the particular scale of hours, days etc.

It might seem that if the value of a commodity is determined by the quantity of labour expended to produce it, it would be the more valuable the more unskilful and lazy the worker who produced it, because he would need more time to complete the article. However, the labour that forms the substance of value is equal human labour, the expenditure of identical human labour-power. The total labour-power of society, which is manifested in the values of the world of commodities, counts here as one homogeneous mass of human labour-power, although composed of innumerable individual units of labour-power. Each of these units is the same as any other, to the extent that it has the character of a socially average unit of labour-power and acts as such, i.e. only needs, in order to produce a commodity, the labour time which is necessary on an average, or in other words is socially necessary. Socially necessary labour-time is the labour-time required to produce any use-value under the conditions of production normal for a given society and with the average degree of skill and intensity of labour prevalent in that society. The introduction of power-looms into England, for example, probably reduced by one half the labour required to convert a given quantity of yarn into woven fabric. In order to do this, the English hand-loom weaver in fact needed the same amount of labour-time as before; but the product of his individual hour of labour now only represented half an hour of social labour, and consequently fell to one half its former value.

What exclusively determines the magnitude of the value of any article is therefore the amount of labour socially necessary, or the labour-time socially necessary for its production.[9] The individual commodity counts here only as an average sample of its kind.[10] Commodities which contain equal quantities of labour, or which can be produced in the same time, have therefore the same value. The value of a commodity is related to the value of any other commodity as the labour-time necessary for the production of the one is related to the labour-time necessary for the production of the other. 'As exchange-values, all commodities are merely definite quantities of *congealed labour-time*.'[11]

---

[9] 'The value of them' (the necessaries of life) 'when they are exchanged the one for another, is regulated by the quantity of labour necessarily required, and commonly taken in producing them' (*Some Thoughts on the Interest of Money in General, and Particularly in the Publick Funds*, London, pp. 36, 37). This remarkable anonymous work of the eighteenth century bears no date. However, it is clear from its contents that it appeared in the reign of George II, about 1739 or 1740.

The value of a commodity would therefore remain constant, if the labour-time required for its production also remained constant. But the latter changes with every variation in the productivity of labour. This is determined by a wide range of circumstances; it is determined amongst other things by the workers' average degree of skill, the level of development of science and its technological application, the social organization of the process of production, the extent and effectiveness of the means of production, and the conditions found in the natural environment. For example, the same quantity of labour is present in eight bushels of corn in favourable seasons and in only four bushels in unfavourable seasons. The same quantity of labour provides more metal in rich mines than in poor. Diamonds are of very rare occurrence on the earth's surface, and hence their discovery costs, on an average, a great deal of labour-time. Consequently much labour is represented in a small volume. Jacob questions whether gold has ever been paid for at its full value.* This applies still more to diamonds. According to Eschwege, the total produce of the Brazilian diamond mines for the eighty years ending in 1823 still did not amount to the price of 1½ years' average produce of the sugar and coffee plantations of the same country,† although the diamonds represented much more labour, therefore more value. With richer mines, the same quantity of labour would be embodied in more diamonds, and their value would fall. If man succeeded, without much labour, in transforming carbon into diamonds,

[10] 'Properly speaking, all products of the same kind form a single mass, and their price is determined in general and without regard to particular circumstances' (Le Trosne, op. cit., p. 893).

[11] Karl Marx, op. cit., p. 6 [English translation, p. 30].

*William Jacob, *An Historical Enquiry into the Production and Consumption of the Precious Metals*, London, 1831, Vol. 2, p. 101.

† This information comes from H. A. M. Merivale, *Lectures on Colonization and Colonies*, London, 1841. Cf. *Grundrisse*, p. 833.

their value might fall below that of bricks. In general, the greater the productivity of labour, the less the labour-time required to produce an article, the less the mass of labour crystallized in that article, and the less its value. Inversely, the less the productivity of labour, the greater the labour-time necessary to produce an article, and the greater its value. The value of a commodity, therefore, varies directly as the quantity, and inversely as the productivity, of the labour which finds its realization within the commodity. (Now we know the *substance* of value. It is *labour*. We know the *measure of its magnitude*. It is *labour-time*. The *form*, which stamps *value* as *exchange-value*, remains to be analysed. But before this we need to develop the characteristics we have already found somewhat more fully.)*

A thing can be a use-value without being a value. This is the case whenever its utility to man is not mediated through labour. Air, virgin soil, natural meadows, unplanted forests, etc. fall into this category. A thing can be useful, and a product of human labour, without being a commodity. He who satisfies his own need with the product of his own labour admittedly creates use-values, but not commodities. In order to produce the latter, he must not only produce use-values, but use-values for others, social use-values. (And not merely for others. The medieval peasant produced a corn-rent for the feudal lord and a corn-tithe for the priest; but neither the corn-rent nor the corn-tithe became commodities simply by being produced for others. In order to become a commodity, the product must be transferred to the other person, for whom it serves as a use-value, through the medium of exchange.)† Finally, nothing can be a value without being an object of utility. If the thing is useless, so is the labour contained in it; the labour does not count as labour, and therefore creates no value.

2. THE DUAL CHARACTER OF THE LABOUR EMBODIED IN COMMODITIES

Initially the commodity appeared to us as an object with a dual character, possessing both use-value and exchange-value. Later on it was seen that labour, too, has a dual character: in so far as it finds its expression in value, it no longer possesses the same characteristics as when it is the creator of use-values. I was the first to point out and examine critically this twofold nature of the labour contained in commodities.[12] As this point is crucial to an understanding of political economy, it requires further elucidation.

---

* The passage in parentheses occurs only in the first edition.

† [Note by Engels to the fourth German edition:] I have inserted the passage in parentheses because, through its omission, the misconception has very frequently arisen that Marx regarded every product consumed by someone other than the producer as a commodity.

Let us take two commodities, such as a coat and 10 yards of linen, and let the value of the first be twice the value of the second, so that, if 10 yards of linen = W, the coat = $2W$.

The coat is a use-value that satisfies a particular need. A specific kind of productive activity is required to bring it into existence. This activity is determined by its aim, mode of operation, object, means and result. We use the abbreviated expression 'useful labour' for labour whose utility is represented by the use-value of its product, or by the fact that its product is a use-value. In this connection we consider only its useful effect.

As the coat and the linen are qualitatively different use-values, so also are the forms of labour through which their existence is mediated – tailoring and weaving. If the use-values were not qualitatively different, hence not the products of qualitatively different forms of useful labour, they would be absolutely incapable of confronting each other as commodities. Coats cannot be exchanged for coats, one use-value cannot be exchanged for another of the same kind.

The totality of heterogeneous use-values or physical commodities reflects a totality of similarly heterogeneous forms of useful labour, which differ in order, genus, species and variety: in short, a social division of labour. This division of labour is a necessary condition for commodity production, although the converse does not hold; commodity production is not a necessary condition for the social division of labour. Labour is socially divided in the primitive Indian community, although the products do not thereby become commodities. Or, to take an example nearer home, labour is systematically divided in every factory, but the workers do not bring about this division by exchanging their individual products. Only the products of mutually independent acts of labour, performed in isolation, can confront each other as commodities.

To sum up, then: the use-value of every commodity contains

---

12. Karl Marx, op. cit., pp. 12, 13, and passim [English translation, pp. 41, 42].

useful labour, i.e. productive activity of a definite kind, carried on with a definite aim. Use-values cannot confront each other as commodities unless the useful labour contained in them is qualitatively different in each case. In a society whose products generally assume the form of commodities, i.e. in a society of commodity producers, this qualitative difference between the useful forms of labour which are carried on independently and privately by individual producers develops into a complex system, a social division of labour.

It is moreover a matter of indifference whether the coat is worn by the tailor or by his customer. In both cases it acts as a use-value. So, too, the relation between the coat and the labour that produced it is not in itself altered when tailoring becomes a special trade, an independent branch of the social division of labour. Men made clothes for thousands of years, under the compulsion of the need for clothing, without a single man ever becoming a tailor. But the existence of coats, of linen, of every element of material wealth not provided in advance by nature, had always to be mediated through a specific productive activity appropriate to its purpose, a productive activity that assimilated particular natural materials to particular human requirements. Labour, then, as the creator of use-values, as useful labour, is a condition of human existence which is independent of all forms of society; it is an eternal natural necessity which mediates the metabolism between man and nature, and therefore human life itself.

Use-values like coats, linen, etc., in short, the physical bodies of commodities, are combinations of two elements, the material provided by nature, and labour. If we subtract the total amount of useful labour of different kinds which is contained in the coat, the linen, etc., a material substratum is always left. This substratum is furnished by nature without human intervention. When man engages in production, he can only proceed as nature does herself, i.e. he can only change the form of the materials.[13] Furthermore, even in this work of modification he is constantly helped by natural forces. Labour is therefore not the only source of material wealth, i.e. of the use-values it produces. As William Petty says, labour is the father of material wealth, the earth is its mother.*

---

[13] 'All the phenomena of the universe, whether produced by the hand of man or indeed by the universal laws of physics, are not to be conceived of as acts of creation but solely as a reordering of matter. Composition and separation are the only elements found by the human mind whenever it analyses the notion of reproduction; and so it is with the reproduction of value' (use-value, although Verri himself, in this polemic against the Physiocrats, is not quite certain of the kind of value he is refer ing to) 'and wealth, whether earth, air and water are turned into corn in the fields, or the secretions of an insect are turned into silk by the hand of man, or some small pieces of metal are

Let us now pass from the commodity as an object of utility to the value of commodities.

We have assumed that the coat is worth twice as much as the linen. But this is merely a quantitative difference, and does not concern us at the moment. We shall therefore simply bear in mind that if the value of a coat is twice that of 10 yards of linen, 20 yards of linen will have the same value as a coat. As values, the coat and the linen have the same substance, they are the objective expressions of homogeneous labour. But tailoring and weaving are qualitatively different forms of labour. There are, however, states of society in which the same man alternately makes clothes and weaves. In this case, these two different modes of labour are only modifications of the labour of the same individual and not yet fixed functions peculiar to different individuals, just as the coat our tailor makes today, and the pair of trousers he makes tomorrow, require him only to vary his own individual labour. Moreover, we can see at a glance that in our capitalist society a given portion of labour is supplied alternately in the form of tailoring and in the form of weaving, in accordance with changes in the direction of the demand for labour. This change in the form of labour may well not take place without friction, but it must take place.

If we leave aside the determinate quality of productive activity, and therefore the useful character of the labour, what remains is its quality of being an expenditure of human labour-power. Tailoring and weaving, although they are qualitatively different productive activities, are both a productive expenditure of human brains, muscles, nerves, hands etc., and in this sense both human labour. They are merely two different forms of the expenditure of human labour-power. Of course, human labour-power must itself

---

arranged together to form a repeating watch' (Pietro Verri, *Meditazioni sulla economia politica* – first printed in 1771 – in Custodi's edition of the Italian economists, *Parte moderna*, Vol. 15, pp. 21, 22).

---

* *A Treatise of Taxes and Contributions*, published anonymously by William Petty, London, 1667, p. 47.

have attained a certain level of development before it can be expended in this or that form. But the value of a commodity represents human labour pure and simple, the expenditure of human labour in general. And just as, in civil society, a general or a banker plays a great part but man as such plays a very mean part,[14] so, here too, the same is true of human labour. It is the expenditure of simple labour-power, i.e. of the labour-power possessed in his bodily organism by every ordinary man, on the average, without being developed in any special way. *Simple average labour*, it is true, varies in character in different countries and at different cultural epochs, but in a particular society it is given. More complex labour counts only as *intensified*, or rather *multiplied* simple labour, so that a smaller quantity of complex labour is considered equal to a larger quantity of simple labour. Experience shows that this reduction is constantly being made. A commodity may be the outcome of the most complicated labour, but through its *value* it is posited as equal to the product of simple labour, hence it represents only a specific quantity of simple labour.[15] The various proportions in which different kinds of labour are reduced to simple labour as their unit of measurement are established by a social process that goes on behind the backs of the producers; these proportions therefore appear to the producers to have been handed down by tradition. In the interests of simplification, we shall henceforth view every form of labour-power directly as simple labour-power; by this we shall simply be saving ourselves the trouble of making the reduction.

Just as, in viewing the coat and the linen as values, we abstract from their different use-values, so, in the case of the labour represented by those values, do we disregard the difference between its useful forms, tailoring and weaving. The use-values coat and linen are combinations of, on the one hand, productive activity with a definite purpose, and, on the other, cloth and yarn; the values coat and linen, however, are merely congealed quantities of homogeneous labour. In the same way, the labour contained in these values does not count by virtue of its productive relation to cloth and yarn, but only as being an expenditure of human labour-power. Tailoring and weaving are the formative elements in the use-values coat and linen, precisely because these two kinds of labour are of different qualities; but only in so far as abstraction is made from their particular qualities, only in so far as both possess the same quality of being human labour, do tailoring and weaving form the substance of the values of the two articles mentioned.

---

[14] Cf. Hegel, *Philosophie des Rechts*, Berlin, 1840, p. 250, para. 190.*

[15] The reader should note that we are not speaking here of the wages or value the worker receives for (e.g.) a day's labour, but of the value of the commodity in which his day of labour is objectified. At this stage of our presentation, the category of wages does not exist at all.

*Hegel says here: 'In civil society as a whole, at the standpoint of needs, what we have before us is the composite idea which we call man. Thus this is the first time, and indeed the only time, to speak of man in this sense' (*Hegel's Philosophy of Right*, tr. T. M. Knox, Oxford, 1952, p. 127).

Coats and linen, however, are not merely values in general, but values of definite magnitude, and, following our assumption, the coat is worth twice as much as the 10 yards of linen. Why is there this difference in value? Because the linen contains only half as much labour as the coat, so that labour-power had to be expended twice as long to produce the second as to produce the first.

While, therefore, with reference to use-value, the labour contained in a commodity counts only qualitatively, with reference to value it counts only quantitatively, once it has been reduced to human labour pure and simple. In the former case it was a matter of the 'how' and the 'what' of labour, in the latter of the 'how much', of the temporal duration of labour. Since the magnitude of the value of a commodity represents nothing but the quantity of labour embodied in it, it follows that all commodities, when taken in certain proportions, must be equal in value.

If the productivity of all the different sorts of useful labour required, let us say, for the production of a coat remains unchanged, the total value of the coats produced will increase along with their quantity. If one coat represents *x* days' labour, two coats will represent 2*x* days' labour, and so on. But now assume that the duration of the labour necessary for the production of a coat is doubled or halved. In the first case, one coat is worth as much as two coats were before; in the second case two coats are only worth as much as one was before, although in both cases one coat performs the same service, and the useful labour contained in it remains of the same quality. One change has taken place, however: a change in the quantity of labour expended to produce the article.

In itself, an increase in the quantity of use-values constitutes an increase in material wealth. Two coats will clothe two men, one coat will only clothe one man, etc. Nevertheless, an increase in the amount of material wealth may correspond to a simultaneous fall in the magnitude of its value. This contradictory movement arises out of the twofold character of labour. By 'productivity' of course, we always mean the productivity of concrete useful labour; in reality this determines only the degree of effectiveness of productive activity directed towards a given purpose within a given period of time. Useful labour becomes, therefore, a more or less abundant source of products in direct proportion as its productivity rises or falls. As against this, however, variations in productivity have no impact whatever on the labour itself represented in value. As productivity is an attribute of labour in its concrete useful form, it naturally ceases to have any bearing on that labour as soon as we abstract from its concrete useful form. The same labour, therefore, performed for the same length of time, always yields the same amount of value, independently of any variations in productivity. But it provides different quantities of use-values during equal periods of time; more, if productivity rises; fewer, if it falls. For this reason, the same change in productivity which increases the fruitfulness of labour, and therefore the amount of use-values produced by it, also brings about a reduction in the value of this increased total amount, if it cuts down the total amount of labour-time necessary to produce the use-values. The converse also holds.

On the one hand, all labour is an expenditure of human labour-power, in the physiological sense, and it is in this quality of being equal, or abstract, human labour that it forms the value of commodities. On the other hand, all labour is an expenditure of human labour-power in a particular form and with a definite aim, and it is in this quality of being concrete useful labour that it produces use-values.[16]

[16] In order to prove that 'labour alone is the ultimate and real standard by which the value of all commodities can at all times and places be estimated and compared', Adam Smith* says this: 'Equal quantities of labour, at all times and places, must have the same value for the labourer. In his ordinary state of health, strength and activity; in the ordinary degree of his skill and dexterity, he must always lay down the same portion of his ease, his liberty, and his happiness' (*Wealth of Nations*, Bk I, Ch. 5 [pp. 104–5]). On the one hand, Adam Smith here (but not everywhere) confuses his determination of value by the quantity of labour expended in the production of commodities with the determination of the values of commodities by the value of labour, and therefore endeavours to prove that equal quantities of labour always have the same

*Here, as elsewhere occasionally, Marx quotes an English author in German. This explains certain slight divergences from the original English text.

3. THE VALUE-FORM, OR EXCHANGE-VALUE

Commodities come into the world in the form of use-values or material goods, such as iron, linen, corn, etc. This is their plain, homely, natural form. However, they are only commodities because they have a dual nature, because they are at the same time objects of utility and bearers of value. Therefore they only appear as commodities, or have the form of commodities, in so far as they possess a double form, i.e. natural form and value form.

The objectivity of commodities as values differs from Dame Quickly in the sense that 'a man knows not where to have it'.* Not an atom of matter enters into the objectivity of commodities as values; in this it is the direct opposite of the coarsely sensuous objectivity of commodities as physical objects. We may twist and turn a single commodity as we wish; it remains impossible to grasp it as a thing possessing value. However, let us remember that commodities possess an objective character as values only in so far as they are all expressions of an identical social substance, human labour, that their objective character as values is therefore

---

value. On the other hand, he has a suspicion that, in so far as labour manifests itself in the value of commodities, it only counts as an expenditure of labour-power; but then again he views this expenditure merely as the sacrifice of rest, freedom and happiness, not as also man's normal life-activity. Of course, he has the modern wage-labourer in mind. Adam Smith's anonymous predecessor, cited in note 9, is much nearer the mark when he says: 'One man has employed himself a week in providing this necessary of life . . . and he that gives him some other in exchange, cannot make a better estimate of what is a proper equivalent, than by computing what cost him just as much labour and time: which in effect is no more than exchanging one man's labour in one thing for a time certain, for another man's labour in another thing for the same time' (*Some Thoughts on the Interest of Money in General etc.*, p. 39). [Note by Engels to the fourth German edition:] The English language has the advantage of possessing two separate words for these two different aspects of labour. Labour which creates use-values and is qualitatively determined is called 'work' as opposed to 'labour'; labour which creates value and is only measured quantitatively is called 'labour', as opposed to 'work'.†

†Unfortunately, English usage does not always correspond to Engels' distinction. We have tried to adopt it where possible.

---

*Falstaff: Why, she's neither fish nor flesh; a man knows not where to have her.

Dame Quickly: Thou art an unjust man in saying so: thou or any man knows where to have me, thou knave, thou!

(*Henry IV*, Part 1, Act 3, Scene 3.)

purely social. From this it follows self-evidently that it can only appear in the social relation between commodity and commodity. In fact we started from exchange-value, or the exchange relation of commodities, in order to track down the value that lay hidden within it. We must now return to this form of appearance of value.

Everyone knows, if nothing else, that commodities have a common value-form which contrasts in the most striking manner with the motley natural forms of their use-values. I refer to the money-form. Now, however, we have to perform a task never even attempted by bourgeois economics. That is, we have to show the origin of this money-form, we have to trace the development of the expression of value contained in the value-relation of commodities from its simplest, almost imperceptible outline to the dazzling money-form. When this has been done, the mystery of money will immediately disappear.

The simplest value-relation is evidently that of one commodity to another commodity of a different kind (it does not matter which one). Hence the relation between the values of two commodities supplies us with the simplest expression of the value of a single commodity.

(a) The Simple, Isolated, or Accidental Form of Value

x commodity A = y commodity B or: x commodity A is worth y commodity B.

(20 yards of linen = 1 coat, or: 20 yards of linen are worth 1 coat)

(1) *The two poles of the expression of value: the relative form of value and the equivalent form*

The whole mystery of the form of value lies hidden in this simple form. Our real difficulty, therefore, is to analyse it.

Here two different kinds of commodities (in our example the linen and the coat) evidently play two different parts. The linen expresses its value in the coat; the coat serves as the material in which that value is expressed. The first commodity plays an active role, the second a passive one. The value of the first commodity is represented as relative value, in other words the commodity is in the relative form of value. The second commodity fulfils the function of equivalent, in other words it is in the equivalent form.

The relative form of value and the equivalent form are two inseparable moments, which belong to and mutually condition each other; but, at the same time, they are mutually exclusive or opposed extremes, i.e. poles of the expression of value. They are always divided up between the different commodities brought into relation with each other by that expression. I cannot, for example, express the value of linen in linen. 20 yards of linen = 20 yards of linen is not an expression of value. The equation states rather the contrary: 20 yards of linen are nothing but 20 yards of linen, a definite quantity of linen considered as an object of utility. The value of the linen can therefore only be expressed relatively, i.e. in another commodity. The relative form of the value of the linen therefore presupposes that some other commodity confronts it in the equivalent form. On the other hand, this other commodity, which figures as the equivalent, cannot simultaneously be in the relative form of value. It is not the latter commodity whose value is being expressed. It only provides the material in which the value of the first commodity is expressed.

Of course, the expression 20 yards of linen = 1 coat, or 20 yards of linen are worth 1 coat, also includes its converse: 1 coat = 20 yards of linen, or 1 coat is worth 20 yards of linen. But in this case I must reverse the equation, in order to express the value of the coat relatively; and, if I do that, the linen becomes the equivalent instead of the coat. The same commodity cannot, therefore, simultaneously appear in both forms in the same expression of value. These forms rather exclude each other as polar opposites.

Whether a commodity is in the relative form or in its opposite, the equivalent form, entirely depends on its actual position in the expression of value. That is, it depends on whether it is the commodity whose value is being expressed, or the commodity in which value is being expressed.

(2) *The relative form of value*

(i) *The content of the relative form of value* In order to find out how the simple expression of the value of a commodity lies hidden in the value-relation between two commodities, we must, first of all, consider the value-relation quite independently of its quantitative aspect. The usual mode of procedure is the precise opposite of this: nothing is seen in the value-relation but the proportion in which definite quantities of two sorts of commodity count as equal to each other. It is overlooked that the magnitudes of different things only become comparable in quantitative terms when they have been reduced to the same unit. Only as expressions of the same unit do they have a common denominator, and are therefore commensurable magnitudes.[17]

Whether 20 yards of linen = 1 coat or = 20 coats or = x coats, i.e. whether a given quantity of linen is worth few or many coats, it is always implied, whatever the proportion, that the linen and the coat, as magnitudes of value, are expressions of the same unit, things of the same nature. Linen = coat is the basis of the equation.

But these two qualitatively equated commodities do not play the same part. It is only the value of the linen that is expressed. And how? By being related to the coat as its 'equivalent', or 'the thing exchangeable' with it. In this relation the coat counts as the form of existence of value, as the material embodiment of value, for only as such is it the same as the linen. On the other hand, the linen's own existence as value comes into view or receives an independent expression, for it is only as value that it can be related to the coat as being equal in value to it, or exchangeable with it. In the same way, butyric acid is a different substance from propyl formate. Yet both are made up of the same chemical substances, carbon (C), hydrogen (H) and oxygen (O). Moreover, these substances are combined together in the same proportions in each case, namely $C_4H_8O_2$. If now butyric acid were to be equated with propyl formate, then, in the first place, propyl formate would count in this relation only as a form of existence of $C_4H_8O_2$; and in the second place, it would thereby be asserted that butyric acid also consists of $C_4H_8O_2$. Thus by equating propyl formate with butyric acid one would be expressing their chemical composition as opposed to their physical formation.

If we say that, as values, commodities are simply congealed quantities of human labour, our analysis reduces them, it is true, to the level of abstract value, but does not give them a form of value distinct from their natural forms. It is otherwise in the value relation of one commodity to another. The first commodity's value character emerges here through its own relation to the second commodity.

---

[17] The few economists, such as S. Bailey, who have concerned themselves with the analysis of the form of value have been unable to arrive at any result, firstly because they confuse the form of value with value itself, and secondly because, under the coarse influence of the practical bourgeois, they give their attention from the outset, and exclusively, to the quantitative aspect of the question. 'The command of quantity . . . constitutes value' (*Money and Its Vicissitudes*, London, 1837, p. 11). Written by S. Bailey.

By equating, for example, the coat as a thing of value to the linen, we equate the labour embedded in the coat with the labour embedded in the linen. Now it is true that the tailoring which makes the coat is concrete labour of a different sort from the weaving which makes the linen. But the act of equating tailoring with weaving reduces the former in fact to what is really equal in the two kinds of labour, to the characteristic they have in common of being human labour. This is a roundabout way of saying that weaving too, in so far as it weaves value, has nothing to distinguish it from tailoring, and, consequently, is abstract human labour. It is only the expression of equivalence between different sorts of commodities which brings to view the specific character of value-creating labour, by actually reducing the different kinds of labour embedded in the different kinds of commodity to their common quality of being human labour in general.[18]

However, it is not enough to express the specific character of the labour which goes to make up the value of the linen. Human labour-power in its fluid state, or human labour, creates value, but is not itself value. It becomes value in its coagulated state, in objective form. The value of the linen as a congealed mass of human labour can be expressed only as an 'objectivity' [*Gegenständlichkeit*], a thing which is materially different from the linen itself and yet common to the linen and all other commodities. The problem is already solved.

When it is in the value-relation with the linen, the coat counts qualitatively as the equal of the linen, it counts as a thing of the same nature, because it is a value. Here it is therefore a thing in which value is manifested, or which represents value in its tangible natural form. Yet the coat itself, the physical aspect of the coat-commodity, is purely a use-value. A coat as such no more expresses value than does the first piece of linen we come across. This proves only that, within its value-relation to the linen, the coat signifies more than it does outside it, just as some men count for more when inside a gold-braided uniform than they do otherwise.

---

[18] One of the first economists, after William Petty,* to have seen through the nature of value, the famous Franklin, says this: 'Trade in general being nothing else but the exchange of labour for labour, the value of all things is ... most justly measured by labour' (*The Works of B. Franklin etc.*, edited by Sparks, Boston, 1836, Vol. 2, p. 267). Franklin is not aware that in measuring the value of everything 'in labour' he makes abstraction from any difference in the kinds of labour exchanged – and thus reduces them all to equal human labour. Yet he states this without knowing it. He speaks first of 'the one labour', then of 'the other labour', and finally of 'labour', without further qualification, as the substance of the value of everything.

*Sir William Petty (1623–87), English economist and statistician, regarded by Marx as the founder of modern political economy (see below, p. 174, n. 34). 'Petty recognizes labour as the source of material wealth' but misapprehends the source of exchange-value (Karl Marx, op. cit., pp. 52–4).

In the production of the coat, human labour-power, in the shape of tailoring, has in actual fact been expended. Human labour has therefore been accumulated in the coat. From this point of view, the coat is a 'bearer of value', although this property never shows through, even when the coat is at its most threadbare. In its value-relation with the linen, the coat counts only under this aspect, counts therefore as embodied value, as the body of value [*Wertkörper*]. Despite its buttoned-up appearance, the linen recognizes in it a splendid kindred soul, the soul of value. Nevertheless, the coat cannot represent value towards the linen unless value, for the latter, simultaneously assumes the form of a coat. An individual, A, for instance, cannot be 'your majesty' to another individual, B, unless majesty in B's eyes assumes the physical shape of A, and, moreover, changes facial features, hair and many other things, with every new 'father of his people'.

Hence, in the value-relation, in which the coat is the equivalent of the linen, the form of the coat counts as the form of value. The value of the commodity linen is therefore expressed by the physical body of the commodity coat, the value of one by the use-value of the other. As a use-value, the linen is something palpably different from the coat; as value, it is identical with the coat, and therefore looks like the coat. Thus the linen acquires a value-form different from its natural form. Its existence as value is manifested in its equality with the coat, just as the sheep-like nature of the Christian is shown in his resemblance to the Lamb of God.

We see, then, that everything our analysis of the value of commodities previously told us is repeated by the linen itself, as soon as it enters into association with another commodity, the coat. Only it reveals its thoughts in a language with which it alone is familiar, the language of commodities. In order to tell us that labour creates its own value in its abstract quality of being human labour, it says that the coat, in so far as it counts as its equal, i.e. is value, consists of the same labour as it does itself. In order to inform us that its sublime objectivity as a value differs from its stiff and starchy existence as a body, it says that value has the appearance of a coat, and therefore that in so far as the linen itself is an object of value [*Wertding*], it and the coat are as like as two peas. Let us note, incidentally, that the language of commodities also has, apart from Hebrew, plenty of other more or less correct dialects. The German word '*Wertsein*' (to be worth), for instance, brings out less strikingly than the Romance verb '*valere*', '*valer*', '*valoir*' that the equating of commodity B with commodity A is the expression of value proper to commodity A. *Paris vaut bien une messe*!*

By means of the value-relation, therefore, the natural form of commodity B becomes the value-form of commodity A, in other words the physical body of commodity B becomes a mirror for the value of commodity A.[19] Commodity A, then, in entering into a relation with commodity B as an object of value [*Wertkörper*], as a materialization of human labour, makes the use-value B into the material through which its own value is expressed. The value of commodity A, thus expressed in the use-value of commodity B, has the form of relative value.

(ii) *The quantitative determinacy of the relative form of value*

Every commodity whose-value is to be expressed is a useful object of a given quantity, for instance 15 bushels of corn, or 100 lb. of coffee. A given quantity of any commodity contains a definite quantity of human labour. Therefore the form of value must not only express value in general, but also quantitatively determined value, i.e. the magnitude of value. In the value-relation of commodity A to commodity B, of the linen to the coat, therefore, not only is the commodity-type coat equated with the linen in qualitative terms as an object of value as such, but also a definite quantity of the object of value or equivalent, 1 coat for example, is equated with a definite quantity of linen, such as 20 yards. The equation 20

[19] In a certain sense, a man is in the same situation as a commodity. As he neither enters into the world in possession of a mirror, nor as a Fichtean philosopher who can say 'I am I', a man first sees and recognizes himself in another man. Peter only relates to himself as a man through his relation to another man, Paul, in whom he recognizes his likeness. With this, however, Paul also becomes from head to toe, in his physical form as Paul, the form of appearance of the species man for Peter.

---

*'Paris is certainly worth a mass.' Henry IV's supposed words on his conversion to Roman Catholicism in 1593.

yards of linen = 1 coat, or 20 yards of linen are worth 1 coat, presupposes the presence in 1 coat of exactly as much of the substance of value as there is in 20 yards of linen, implies therefore that the quantities in which the two commodities are present have cost the same amount of labour or the same quantity of labour-time. But the labour-time necessary for the production of 20 yards of linen or 1 coat varies with every change in the productivity of the weaver or the tailor. The influence of such changes on the relative expression of the magnitude of value must now be investigated more closely.

I. Let the value of the linen change[20] while the value of the coat remains constant. If the labour-time necessary for the production of linen be doubled, as a result of the increasing infertility of flax-growing soil for instance, its value will also be doubled. Instead of the equation 20 yards of linen = 1 coat, we should have 20 yards of linen = 2 coats, since 1 coat would now contain only half as much labour-time as 20 yards of linen. If, on the other hand, the necessary labour-time be reduced by one half, as a result of improved looms for instance, the value of the linen will fall by one half. In accordance with this the equation will now read 20 yards of linen = ½ coat. The relative value of commodity A, i.e. its value expressed in commodity B, rises and falls in direct relation to the value of A, if the value of B remains constant.

II. Let the value of the linen remain constant, while the value of the coat changes. If, under these circumstances, the labour-time necessary for the production of a coat is doubled, as a result, for instance, of a poor crop of wool, we should have, instead of 20 yards of linen = 1 coat, 20 yards of linen = ½ coat. If, on the other hand, the value of the coat sinks by one half, then 20 yards of linen = 2 coats. Hence, if the value of commodity A remains constant, its relative value, as expressed in commodity B, rises and falls in inverse relation to the change in the value of B.

If we compare the different cases examined under headings I and II, it emerges that the same change in the magnitude of relative value may arise from entirely opposed causes. Thus the equation 20 yards of linen = 1 coat becomes 20 yards of linen = 2 coats, either because the value of the linen has doubled or because the value of the coat has fallen by one half, and it becomes 20 yards of linen = $\frac{1}{2}$ coat, either because the value of the linen has fallen by one half, or because the value of the coat has doubled.

---

[20] Here, as occasionally also on previous pages, we use the expression 'value' for quantitatively determined values, i.e. for the magnitude of value.

III. Let the quantities of labour necessary for the production of the linen and the coat vary simultaneously in the same direction and the same proportion. In this case, 20 yards of linen = 1 coat, as before, whatever change may have taken place in their respective values. Their change of value is revealed only when they are compared with a third commodity, whose value has remained constant. If the values of all commodities rose or fell simultaneously, and in the same proportion, their relative values would remain unaltered. The change in their real values would be manifested by an increase or decrease in the quantity of commodities produced within the same labour-time.

IV. The labour-time necessary for the production respectively of the linen and the coat, and hence their values, may vary simultaneously in the same direction, but to an unequal degree, or in opposite directions, and so on. The influence of all possible combinations of this kind on the relative value of a commodity can be worked out simply by applying cases I, II and III.

Thus real changes in the magnitude of value are neither unequivocally nor exhaustively reflected in their relative expression, or, in other words, in the magnitude of the relative value. The relative value of a commodity may vary, although its value remains constant. Its relative value may remain constant, although its value varies; and finally, simultaneous variations in the magnitude of its value and in the relative expression of that magnitude do not by any means have to correspond at all points.[21]

[21] The vulgar economists* have exploited this lack of congruence between the magnitude of value and its relative expression with their customary ingenuity. For example: 'Once admit that A falls, because B, with which it is exchanged, rises, while no less labour is bestowed in the meantime on A, and your general principle of value falls to the ground ... If he [Ricardo] allowed that when A rises in value relatively to B, B falls in value relatively to A, he cut away the ground on which he rested his grand proposition, that the value of a commodity is ever determined by the labour embodied in it; for if a change in the cost of A alters not only its own value in relation to B, for which it is exchanged, but also the value of B relatively to that of A, though no change has taken place in the quantity of labour to produce B, then not only the doctrine falls to the ground which asserts that the quantity of labour bestowed on an article regulates its value, but also that which affirms the cost of an article to

*Marx explains his use of the term 'vulgar economists' in Section 4 of this chapter, pp. 174–5, n. 34.

(iii) *The equivalent form* We have seen that a commodity A (the linen), by expressing its value in the use-value of a commodity B of a different kind (the coat), impresses upon the latter a form of value peculiar to it, namely that of the equivalent. The commodity linen brings to view its own existence as a value through the fact that the coat can be equated with the linen although it has not assumed a form of value distinct from its own physical form. The coat is directly exchangeable with the linen; in this way the linen in fact expresses its own existence as a value [*Wertsein*]. The equivalent form of a commodity, accordingly, is the form in which it is directly exchangeable with other commodities.

If one kind of commodity, such as a coat, serves as the equivalent of another, such as linen, and coats therefore acquire the characteristic property of being in a form in which they can be directly exchanged with linen, this still by no means provides us with the proportion in which the two are exchangeable. Since the magnitude of the value of the linen is a given quantity, this proportion depends on the magnitude of the coat's value. Whether the coat is expressed as the equivalent and the linen as relative value, or, inversely, the linen is expressed as equivalent and the coat as relative value, the magnitude of the coat's value is determined, as ever, by the labour-time necessary for its production, independently of its value-form. But as soon as the coat takes up the position of the equivalent in the value expression, the magnitude of its value ceases to be expressed quantitatively. On the contrary, the coat now figures in the value equation merely as a definite quantity of some article.

For instance, 40 yards of linen are 'worth' – what? 2 coats. Because the commodity coat here plays the part of equivalent, because the use-value coat counts as the embodiment of value *vis-à-vis* the linen, a definite number of coats is sufficient to express a definite quantity of value in the linen. Two coats can therefore express the magnitude of value of 40 yards of linen, but they can

---

regulate its value' (J. Broadhurst, *Political Economy*, London, 1842, pp. 11 and 14).

Mr Broadhurst might just as well say: consider the fractions 10/20, 10/50, 10/100 etc. The number 10 remains unchanged, and yet its proportional magnitude, its magnitude in relation to the numbers 20, 50, 100 continually diminishes. Therefore, the great principle that the magnitude of a whole number, such as 10, is 'regulated' by the number of times the number 1 is contained in it falls to the ground.

never express the magnitude of their own value. Because they had a superficial conception of this fact, i.e. because they considered that in the equation of value the equivalent always has the form of a simple quantity of some article, of a use-value, Bailey and many of his predecessors and followers were misled into seeing the expression of value as merely a quantitative relation;* whereas in fact the equivalent form of a commodity contains no quantitative determinant of value.

The first peculiarity which strikes us when we reflect on the equivalent form is this, that use-value becomes the form of appearance of its opposite, value.

The natural form of the commodity becomes its value-form. But, note well, this substitution only occurs in the case of a commodity B (coat, or maize, or iron, etc.) when some other commodity A (linen etc.) enters into a value-relation with it, and then only within the limits of this relation. Since a commodity cannot be related to itself as equivalent, and therefore cannot make its own physical shape into the expression of its own value, it must be related to another commodity as equivalent, and therefore must make the physical shape of another commodity into its own value-form.

Let us make this clear with the example of a measure which is applied to commodities as material objects, i.e. as use-values. A sugar-loaf, because it is a body, is heavy and therefore possesses weight; but we can neither take a look at this weight nor touch it. We then take various pieces of iron, whose weight has been determined beforehand. The bodily form of the iron, considered for itself, is no more the form of appearance of weight than is the sugar-loaf. Nevertheless, in order to express the sugar-loaf as a weight, we put it into a relation of weight with the iron. In this relation, the iron counts as a body representing nothing but weight. Quantities of iron therefore serve to measure the weight of the sugar, and represent, in relation to the sugar-loaf, weight in its pure form, the form of manifestation of weight. This part is played by the iron only within this relation, i.e. within the relation into which the sugar, or any other body whose weight is to be found, enters with the iron. If both objects lacked weight, they

---

*'The most superficial form of exchange-value, that is the *quantitative relation* in which commodities exchange with one another, *constitutes*, according to Bailey, their value' (Karl Marx, *Theories of Surplus-Value*, Part III, London, 1972, p. 129).

could not enter into this relation, hence the one could not serve to express the weight of the other. When we throw both of them into the scales, we see in reality that considered as weight they are the same, and therefore that, taken in the appropriate proportions, they have the same weight. Just as the body of the iron, as a measure of weight, represents weight alone, in relation to the sugar-loaf, so, in our expression of value, the body of the coat represents value alone.

Here, however, the analogy ceases. In the expression of the weight of the sugar-loaf, the iron represents a natural property common to both bodies, their weight; but in the expression of value of the linen the coat represents a supra-natural property: their value, which is something purely social.

The relative value-form of a commodity, the linen for example, expresses its value-existence as something wholly different from its substance and properties, as the quality of being comparable with a coat for example; this expression itself therefore indicates that it conceals a social relation. With the equivalent form the reverse is true. The equivalent form consists precisely in this, that the material commodity itself, the coat for instance, expresses value just as it is in its everyday life, and is therefore endowed with the form of value by nature itself. Admittedly, this holds good only within the value-relation, in which the commodity linen is related to the commodity coat as its equivalent.[22] However, the properties of a thing do not arise from its relations to other things, they are, on the contrary, merely activated by such relations. The coat, therefore, seems to be endowed with its equivalent form, its property of direct exchangeability, by nature, just as much as its property of being heavy or its ability to keep us warm. Hence the mysteriousness of the equivalent form, which only impinges on the crude bourgeois vision of the political economist when it confronts him in its fully developed shape, that of money. He then seeks to explain away the mystical character of gold and silver by substituting for them less dazzling commodities, and, with ever-renewed satisfaction, reeling off a catalogue of all the inferior commodities which have played the role of the equivalent at one time or another. He does not suspect that even the simplest expression of value, such as 20 yards of linen = 1 coat, already presents the riddle of the equivalent form for us to solve.

---

[22] Determinations of reflection [*Reflexionsbestimmungen*] of this kind are altogether very curious. For instance, one man is king only because other men stand in the relation of subjects to him. They, on the other hand, imagine that they are subjects because he is king.*

*Cf. Hegel, *Science of Logic*, tr. A. V. Miller, London, 1969, pp. 409–11, where the determinations of reflection are stated to be 'not of a qualitative kind . . . but determinatenesses which are themselves relations'.

The body of the commodity, which serves as the equivalent, always figures as the embodiment of abstract human labour, and is always the product of some specific useful and concrete labour. This concrete labour therefore becomes the expression of abstract human labour. If the coat is merely abstract human labour's realization, the tailoring actually realized in it is merely abstract human labour's form of realization. In the expression of value of the linen, the usefulness of tailoring consists, not in making clothes, and thus also people, but in making a physical object which we at once recognize as value, as a congealed quantity of labour, therefore, which is absolutely indistinguishable from the labour objectified in the value of the linen. In order to act as such a mirror of value, tailoring itself must reflect nothing apart from its own abstract quality of being human labour.

Human labour-power is expended in the form of tailoring as well as in the form of weaving. Both therefore possess the general property of being human labour, and they therefore have to be considered in certain cases, such as the production of value, solely from this point of view. There is nothing mysterious in this. But in the value expression of the commodity the question is stood on its head. In order to express the fact that, for instance, weaving creates the value of linen through its general property of being human labour rather than in its concrete form as weaving, we contrast it with the concrete labour which produces the equivalent of the linen, namely tailoring. Tailoring is now seen as the tangible form of realization of abstract human labour.

The equivalent form therefore possesses a second peculiarity: in it, concrete labour becomes the form of manifestation of its opposite, abstract human labour.

But because this concrete labour, tailoring, counts exclusively as the expression of undifferentiated human labour, it possesses the characteristic of being identical with other kinds of labour, such as the labour embodied in the linen. Consequently, although, like all other commodity-producing labour, it is the labour of private individuals, it is nevertheless labour in its directly social form. It is precisely for this reason that it presents itself to us in the shape of a product which is directly exchangeable with other commodities.

Thus the equivalent form has a third peculiarity: private labour takes the form of its opposite, namely labour in its directly social form.

The two peculiarities of the equivalent form we have just developed will become still clearer if we go back to the great investigator who was the first to analyse the value-form, like so many other forms of thought, society and nature. I mean Aristotle.

In the first place, he states quite clearly that the money-form of the commodity is only a more developed aspect of the simple form of value, i.e. of the expression of the value of a commodity in some other commodity chosen at random, for he says:

5 beds = 1 house

(Κλῖναι πέντε ἀντὶ οἰκίας)

is indistinguishable from

5 beds = a certain amount of money

(Κλῖναι πέντε ἀντὶ . . . ὅσου αἱ πέντε κλῖναι)

He further sees that the value-relation which provides the framework for this expression of value itself requires that the house should be qualitatively equated with the bed, and that these things, being distinct to the senses, could not be compared with each other as commensurable magnitudes if they lacked this essential identity. 'There can be no exchange,' he says, 'without equality, and no equality without commensurability' ('οὔτ' ἰσοτης μὴ οὔσης συμμετρίας'). Here, however, he falters, and abandons the further analysis of the form of value. 'It is, however, in reality, impossible ("τῆ μὲν οὖν ἀληθείᾳ ἀδύνατον") that such unlike things can be commensurable,' i.e. qualitatively equal. This form of equation can only be something foreign to the true nature of the things, it is therefore only 'a makeshift for practical purposes'.*

Aristotle therefore himself tells us what prevented any further analysis: the lack of a concept of value. What is the homogeneous element, i.e. the common substance, which the house represents from the point of view of the bed, in the value expression for the bed? Such a thing, in truth, cannot exist, says Aristotle. But why not? Towards the bed, the house represents something equal, in so far as it represents what is really equal, both in the bed and the house. And that is – human labour.

However, Aristotle himself was unable to extract this fact, that,

---

*The quotations in this paragraph are from Aristotle, *Nicomachean Ethics*, Bk V, Ch. 5 (Loeb edition, London, 1926, pp. 287–9).

in the form of commodity-values, all labour is expressed as equal human labour and therefore as labour of equal quality, by inspection from the form of value, because Greek society was founded on the labour of slaves, hence had as its natural basis the inequality of men and of their labour-powers. The secret of the expression of value, namely the equality and equivalence of all kinds of labour because and in so far as they are human labour in general, could not be deciphered until the concept of human equality had already acquired the permanence of a fixed popular opinion. This however becomes possible only in a society where the commodity-form is the universal form of the product of labour, hence the dominant social relation is the relation between men as possessors of commodities. Aristotle's genius is displayed precisely by his discovery of a relation of equality in the value-expression of commodities. Only the historical limitation inherent in the society in which he lived prevented him from finding out what 'in reality' this relation of equality consisted of.

(iv) *The simple form of value considered as a whole* A commodity's simple form of value is contained in its value-relation with another commodity of a different kind, i.e. in its exchange relation with the latter. The value of commodity A is qualitatively expressed by the direct exchangeability of commodity B with commodity A. It is quantitatively expressed by the exchangeability of a specific quantity of commodity B with a given quantity of A. In other words, the value of a commodity is independently expressed through its presentation [*Darstellung*] as 'exchange-value'. When, at the beginning of this chapter, we said in the customary manner that a commodity is both a use-value and an exchange-value, this was, strictly speaking, wrong. A commodity is a use-value or object of utility, and a 'value'. It appears as the twofold thing it really is as soon as its value possesses its own particular form of manifestation, which is distinct from its natural form. This form of manifestation is exchange-value, and the commodity never has this form when looked at in isolation, but only when it is in a value-relation or an exchange relation with a second commodity of a different kind. Once we know this, our manner of speaking does no harm; it serves, rather, as an abbreviation.

Our analysis has shown that the form of value, that is, the expression of the value of a commodity, arises from the nature of commodity-value, as opposed to value and its magnitude arising from their mode of expression as exchange-value. This second view is the delusion both of the Mercantilists (and people like Ferrier, Ganilh, etc.,[23] who have made a modern rehash of Mercantilism) and their antipodes, the modern bagmen of free trade, such as Bastiat and his associates. The Mercantilists place their main emphasis on the qualitative side of the expression of value, hence on the equivalent form of the commodity, which in its finished form is money. The modern pedlars of free trade, on the other hand, who must get rid of their commodities at any price, stress the quantitative side of the relative form of value. For them, accordingly, there exists neither value, nor magnitude of value, anywhere except in its expression by means of the exchange relation, that is, in the daily list of prices current on the Stock Exchange. The Scotsman Macleod,* whose function it is to trick out the confused ideas of Lombard Street in the most learned finery, is a successful cross between the superstitious Mercantilists and the enlightened pedlars of free trade.

A close scrutiny of the expression of the value of commodity A contained in the value-relation of A to B has shown that within that relation the natural form of commodity A figures only as the aspect of use-value, while the natural form of B figures only as the form of value, or aspect of value. The internal opposition between use-value and value, hidden within the commodity, is therefore represented on the surface by an external opposition, i.e. by a relation between two commodities such that the one commodity, *whose own* value is supposed to be expressed, counts directly only as a use-value, whereas the other commodity, *in which* that value is to be expressed, counts directly only as exchange-value. Hence the simple form of value of a commodity is the simple form of appearance of the opposition between use-value and value which is contained within the commodity.

The product of labour is an object of utility in all states of society; but it is only a historically specific epoch of development which presents the labour expended in the production of a useful

[23] F. L. A. Ferrier (*sous-inspecteur des douanes*), *Du gouvernement considéré dans ses rapports avec le commerce*, Paris, 1805; and Charles Ganilh, *Des systèmes d'économie politique*, 2nd edn, Paris, 1821.

---

*H. D. Macleod (1821–1902), opponent of the classical economists, who, Marx says, 'misinterprets the most elementary economic relations to such an extent that he asserts that money in general arises from its most advanced form, that is means of payment' (Karl Marx, *A Contribution to the Critique of Political Economy*, p. 143).

article as an 'objective' property of that article, i.e. as its value. It is only then that the product of labour becomes transformed into a commodity. It therefore follows that the simple form of value of the commodity is at the same time the simple form of value of the product of labour, and also that the development of the commodity-form coincides with the development of the value-form.

We perceive straight away the insufficiency of the simple form of value: it is an embryonic form which must undergo a series of metamorphoses before it can ripen into the price-form.

The expression of the value of commodity A in terms of any other commodity B merely distinguishes the value of A from its use-value, and therefore merely places A in an exchange-relation with any particular single different kind of commodity, instead of representing A's qualitative equality with all other commodities and its quantitative proportionality to them. To the simple relative form of value of a commodity there corresponds the single equivalent form of another commodity. Thus, in the relative expression of value of the linen, the coat only possesses the form of equivalent, the form of direct exchangeability, in relation to this one individual commodity, the linen.

Nevertheless, the simple form of value automatically passes over into a more complete form. Admittedly, this simple form only expresses the value of a commodity A in one commodity of another kind. But what this second commodity is, whether it is a coat, iron, corn, etc., is a matter of complete indifference. Therefore different simple expressions of the value of one and the same commodity arise according to whether that commodity enters into a value-relation with this second commodity or another kind of commodity.[24] The number of such possible expressions is limited only by the number of the different kinds of commodities distinct from it. The isolated expression of A's value is thus transformed into the indefinitely expandable series of different simple expressions of that value.

(b) The Total or Expanded Form of Value

z commodity A $=$ u commodity B or $=$ v commodity C or $=$ w commodity D or $=$ x commodity E or $=$ etc.

---

[24] In Homer, for instance (*Iliad*, VII, 472–5), the value of a thing is expressed in a series of different things.

(20 yards of linen = 1 coat or = 10 lb. tea or = 40 lb. coffee or = 1 quarter of corn or = 2 ounces of gold or = ½ ton of iron or = etc.)

(1) *The expanded relative form of value*

The value of a commodity, the linen for example, is now expressed in terms of innumerable other members of the world of commodities. Every other physical commodity now becomes a mirror of the linen's value.[25] It is thus that this value first shows itself as being, in reality, a congealed quantity of undifferentiated human labour. For the labour which creates it is now explicitly presented as labour which counts as the equal of every other sort of human labour, whatever natural form it may possess, hence whether it is objectified in a coat, in corn, in iron, or in gold. The linen, by virtue of the form of value, no longer stands in a social relation with merely one other kind of commodity, but with the whole world of commodities as well. As a commodity it is a citizen of that world. At the same time, the endless series of expressions of its value implies that, from the point of view of the value of the commodity, the particular form of use-value in which it appears is a matter of indifference.

In the first form, 20 yards of linen = 1 coat, it might well be a purely accidental occurrence that these two commodities are exchangeable in a specific quantitative relation. In the second form, on the contrary, the background to this accidental appearance, essentially different from it, and determining it, immediately shines through. The value of the linen remains unaltered in magnitude, whether expressed in coats, coffee, or iron, or in innumerable different commodities, belonging to as many different owners. The accidental relation between two individual commodity-owners disappears. It becomes plain that it is not the exchange of commodities which regulates the magnitude of their values, but rather the reverse, the magnitude of the value of commodities which regulates the proportion in which they exchange.

---

[25] For this reason we can speak of the coat-value of the linen when its value is expressed in coats, or of its corn-value when expressed in corn, and so on. Every such expression tells us that it is the value of the linen which appears in the use-values coat, corn etc. 'The value of any commodity denoting its relation in exchange, we may speak of it as . . . corn-value, cloth-value, according to the commodity with which it is compared; and hence there are a thousand different kinds of value, as many kinds of value as there are commodities in existence, and all are equally real and equally nominal' (*A Critical Dissertation on the Nature, Measure, and Causes of Value: Chiefly in Reference to the Writings of Mr Ricardo and His Followers. By the Author of Essays on the Formation, etc., of Opinions,* London, 1825, p. 39). S. Bailey, the author of this anonymous work, which in its day created a considerable stir in England, was under the delusion that by pointing to the multiplicity of the relative expressions of the same commodity-value he had obliterated any possibility of a conceptual determination of value. Still, despite the narrowness of his own outlook he was able to put his finger on some serious defects in the Ricardian theory, as is demonstrated by the animosity with which he was attacked by Ricardo's followers, in the *Westminster Review* for example.*

* The *Westminster Review* was founded in 1824 by Bentham and Bowring, as a quarterly journal of orthodox Radicalism. It was Ricardian in economic theory.

(2) *The particular equivalent form*

Each commodity, such as coat, tea, iron, etc., figures in the expression of value of the linen as an equivalent, hence as a physical object possessing value. The specific natural form of each of these commodities is now a particular equivalent form alongside many others. In the same way, the many specific, concrete, and useful kinds of labour contained in the physical commodities now count as the same number of particular forms of realization or manifestation of human labour in general.

(3) *Defects of the total or expanded form of value*

Firstly, the relative expression of value of the commodity is incomplete, because the series of its representations never comes to an end. The chain, of which each equation of value is a link, is liable at any moment to be lengthened by a newly created commodity, which will provide the material for a fresh expression of value. Secondly, it is a motley mosaic of disparate and unconnected expressions of value. And lastly, if, as must be the case, the relative value of each commodity is expressed in this expanded form, it follows that the relative form of value of each commodity is an endless series of expressions of value which are all different from the relative form of value of every other commodity. The defects of the expanded relative form of value are reflected in the corresponding equivalent form. Since the natural form of each particular kind of commodity is one particular equivalent form amongst innumerable other equivalent forms, the only equivalent forms which exist are limited ones, and each of them excludes all the others. Similarly, the specific, concrete, useful kind of labour contained in each particular commodity-equivalent is only a particular kind of labour and therefore not an exhaustive form of appearance of human labour in general. It is true that the completed or total form of appearance of human labour is constituted by the totality of its particular forms of appearance. But in that case it has no single, unified form of appearance.

The expanded relative form of value is, however, nothing but the sum of the simple relative expressions or equations of the first form, such as:

20 yards of linen = 1 coat
20 yards of linen = 10 lb. of tea, etc.

However, each of these equations implies the identical equation in reverse:

1 coat = 20 yards of linen
10 lb. of tea = 20 yards of linen, etc.

In fact, when a person exchanges his linen for many other commodities, and thus expresses its value in a series of other commodities, it necessarily follows that the other owners of commodities exchange them for the linen, and therefore express the values of their various commodities in one and the same third commodity, the linen. If, then, we reverse the series 20 yards of linen = 1 coat, or = 10 lb. of tea, etc., i.e. if we give expression to the converse relation already implied in the series, we get:

(c) The General Form of Value

$$\left.\begin{array}{l} \text{1 coat} \\ \text{10 lb. of tea} \\ \text{40 lb. of coffee} \\ \text{1 quarter of corn} \\ \text{2 ounces of gold} \\ \tfrac{1}{2}\text{ ton of iron} \\ x\text{ commodity A etc.} \end{array}\right\} = \text{20 yards of linen}$$

(1) *The changed character of the form of value*

The commodities now present their values to us, (1) in a simple form, because in a single commodity; (2) in a unified form, because in the same commodity each time. Their form of value is simple and common to all, hence general.

The two previous forms (let us call them A and B) only amounted to the expression of the value of a commodity as something distinct from its own use-value or its physical shape as a commodity.

The first form, A, produced equations like this: 1 coat = 20 yards of linen, 10 lb. of tea = ½ ton of iron. The value of the coat is expressed as comparable with linen,* that of the tea as comparable with iron. But to be comparable with linen and with iron, these expressions of the value of coat and tea, is to be as different as linen is from iron. This form, it is plain, appears in practice only in the early stages, when the products of labour are converted into commodities by accidental occasional exchanges.

The second form, B, distinguishes the value of a commodity from its own use-value more adequately than the first, for the value of the coat now stands in contrast with its natural form in all possible shapes, in the sense that it is equated with linen, iron, tea, in short with everything but itself. On the other hand any expression of value common to all commodities is directly excluded; for, in the expression of value of each commodity, all other commodities now appear only in the form of equivalents. The expanded form of value comes into actual existence for the first time when a particular product of labour, such as cattle, is no longer exceptionally, but habitually, exchanged for various other commodities.

The new form we have just obtained expresses the values of the world of commodities through one single kind of commodity set apart from the rest, through the linen for example, and thus represents the values of all commodities by means of their equality with linen. Through its equation with linen, the value of every commodity is now not only differentiated from its own use-value, but from all use-values, and is, by that very fact, expressed as that which is common to all commodities. By this form, commodities are, for the first time, really brought into relation with each other as values, or permitted to appear to each other as exchange-values.

The two earlier forms express the value of each commodity either in terms of a single commodity of a different kind, or in a series of many commodities which differ from the first one. In both cases it is the private task, so to speak, of the individual

---

*'Comparable with linen' is the expression we have chosen to render *Leinwandgleiches*, 'comparable with iron' renders *Eisengleiches*, and so on. These circumlocutions are unavoidable here.

commodity to give itself a form of value, and it accomplishes this task without the aid of the others, which play towards it the merely passive role of equivalent. The general form of value, on the other hand, can only arise as the joint contribution of the whole world of commodities. A commodity only acquires a general expression of its value if, at the same time, all other commodities express their values in the same equivalent; and every newly emergent commodity must follow suit. It thus becomes evident that because the objectivity of commodities as values is the purely 'social existence' of these things, it can only be expressed through the whole range of their social relations; consequently the form of their value must possess social validity.

In this form, when they are all counted as comparable with the linen, all commodities appear not only as qualitatively equal, as values in general, but also as values of quantitatively comparable magnitude. Because the magnitudes of their values are expressed in one and the same material, the linen, these magnitudes are now reflected in each other. For instance, 10 lb. of tea = 20 yards of linen, and 40 lb. of coffee = 20 yards of linen. Therefore 10 lb. of tea = 40 lb. of coffee. In other words, 1 lb. of coffee contains only a quarter as much of the substance of value, that is, labour, as 1 lb. of tea.

The general relative form of value imposes the character of universal equivalent on the linen, which is the commodity excluded, as equivalent, from the whole world of commodities. Its own natural form is the form assumed in common by the values of all commodities; it is therefore directly exchangeable with all other commodities. The physical form of the linen counts as the visible incarnation, the social chrysalis state, of all human labour. Weaving, the private labour which produces linen, acquires as a result a general social form, the form of equality with all other kinds of labour. The innumerable equations of which the general form of value is composed equate the labour realized in the linen with the labour contained in every other commodity in turn, and they thus convert weaving into the general form of appearance of undifferentiated human labour. In this manner the labour objectified in the values of commodities is not just presented negatively, as labour in which abstraction is made from all the concrete forms and useful properties of actual work. Its own positive nature is explicitly brought out, namely the fact that it is the reduction of all kinds of actual labour to their common character of being human labour in general, of being the expenditure of human labour-power.

The general value-form, in which all the products of labour are presented as mere congealed quantities of undifferentiated human labour, shows by its very structure that it is the social expression of the world of commodities. In this way it is made plain that within this world the general human character of labour forms its specific social character.

(2) *The development of the relative and equivalent forms of value: their interdependence*

The degree of development of the relative form of value, and that of the equivalent form, correspond. But we must bear in mind that the development of the equivalent form is only the expression and the result of the development of the relative form.

The simple or isolated relative form of value of one commodity converts some other commodity into an isolated equivalent. The expanded form of relative value, that expression of the value of one commodity in terms of all other commodities, imprints those other commodities with the form of particular equivalents of different kinds. Finally, a particular kind of commodity acquires the form of universal equivalent, because all other commodities make it the material embodiment of their uniform and universal form of value.

But the antagonism between the relative form of value and the equivalent form, the two poles of the value-form, also develops concomitantly with the development of the value-form itself.

The first form, 20 yards of linen = 1 coat, already contains this antagonism, without as yet fixing it. According to whether we read the same equation forwards or backwards, each of the two commodity poles, such as the linen and the coat, is to be found in the relative form on one occasion, and in the equivalent form on the other occasion. Here it is still difficult to keep hold of the polar antagonism.

In form B, only one commodity at a time can completely expand its relative value, and it only possesses this expanded relative form of value because, and in so far as, all other commodities are, with respect to it, equivalents. Here we can no longer reverse the equation 20 yards of linen = 1 coat without altering its whole character, and converting it from the expanded form into the general form of value.

Finally, the last form, C, gives to the world of commodities a general social relative form of value, because, and in so far as, all commodities except one are thereby excluded from the equivalent form. A single commodity, the linen, therefore has the form of direct exchangeability with all other commodities, in other words it has a directly social form because, and in so far as, no other commodity is in this situation.[26]

The commodity that figures as universal equivalent is on the other hand excluded from the uniform and therefore universal relative form of value. If the linen, or any other commodity serving as universal equivalent, were, at the same time, to share in the relative form of value, it would have to serve as its own equivalent. We should then have: 20 yards of linen = 20 yards of linen, a tautology in which neither the value nor its magnitude is expressed. In order to express the relative value of the universal equivalent, we must rather reverse the form C. This equivalent has no relative form of value in common with other commodities; its value is, rather, expressed relatively in the infinite series of all other physical commodities. Thus the expanded relative form of value, or form B, now appears as the specific relative form of value of the equivalent commodity.

---

[26] It is by no means self-evident that the form of direct and universal exchangeability is an antagonistic form, as inseparable from its opposite, the form of non-direct exchangeability, as the positivity of one pole of a magnet is from the negativity of the other pole. This has allowed the illusion to arise that all commodities can simultaneously be imprinted with the stamp of direct exchangeability, in the same way that it might be imagined that all Catholics can be popes. It is, of course, highly desirable in the eyes of the petty bourgeois, who views the production of commodities as the absolute summit of human freedom and individual independence, that the inconveniences resulting from the impossibility of exchanging commodities directly, which are inherent in this form, should be removed. This philistine utopia is depicted in the socialism of Proudhon, which, as I have shown elsewhere,* does not even possess the merit of originality, but was in fact developed far more successfully long before Proudhon by Gray, Bray and others. Even so, wisdom of this kind is still rife in certain circles under the name of 'science'. No school of thought has thrown around the word 'science' more haphazardly than that of Proudhon, for '*wo Begriffe fehlen, da stellt zur rechten Zeit ein Wort sich ein*'.†

*In Chapter 1 of Marx's 1847 polemic against Proudhon, *The Poverty of Philosophy*.

†'Where thoughts are absent, words are brought in as convenient replacements.' A slightly altered quotation from Goethe, *Faust*, Part I, Scene 4, Faust's Study, lines 1995–6.

(3) *The transition from the general form of value to the money form*

The universal equivalent form is a form of value in general. It can therefore be assumed by any commodity. On the other hand, a commodity is only to be found in the universal equivalent form (form C) if, and in so far as, it is excluded from the ranks of all other commodities, as being their equivalent. Only when this exclusion becomes finally restricted to a specific kind of commodity does the uniform relative form of value of the world of commodities attain objective fixedness and general social validity.

The specific kind of commodity with whose natural form the equivalent form is socially interwoven now becomes the money commodity, or serves as money. It becomes its specific social function, and consequently its social monopoly, to play the part of universal equivalent within the world of commodities. Among the commodities which in form B figure as particular equivalents of the linen, and in form C express in common their relative values in linen, there is one in particular which has historically conquered this advantageous position: gold. If, then, in form C, we replace the linen by gold, we get:

(d) The Money Form

$$\left.\begin{array}{l}\text{20 yards of linen}\\ \text{1 coat}\\ \text{10 lb. of tea}\\ \text{40 lb. of coffee}\\ \text{1 quarter of corn}\\ \tfrac{1}{2}\text{ ton of iron}\\ x\text{ commodity A}\end{array}\right\} = \text{2 ounces of gold}$$

Fundamental changes have taken place in the course of the transition from form A to form B, and from form B to form C. As against this, form D differs not at all from form C, except that now instead of linen gold has assumed the universal equivalent form. Gold is in form D what linen was in form C: the universal equivalent. The advance consists only in that the form of direct and universal exchangeability, in other words the universal equivalent form, has now by social custom finally become entwined with the specific natural form of the commodity gold.

Gold confronts the other commodities as money only because it previously confronted them as a commodity. Like all other commodities it also functioned as an equivalent, either as a single equivalent in isolated exchanges or as a particular equivalent alongside other commodity-equivalents. Gradually it began to serve as universal equivalent in narrower or wider fields. As soon as it had won a monopoly of this position in the expression of value for the world of commodities, it became the money commodity, and only then, when it had already become the money commodity, did form D become distinct from form C, and the general form of value come to be transformed into the money form.

The simple expression of the relative value of a single commodity, such as linen, in a commodity which is already functioning as the money commodity, such as gold, is the price form. The 'price form' of the linen is therefore: 20 yards of linen = 2 ounces of gold, or, if 2 ounces of gold when coined are £2, 20 yards of linen = £2.

The only difficulty in the concept of the money form is that of grasping the universal equivalent form, and hence the general form of value as such, form C. Form C can be reduced by working backwards to form B, the expanded form of value, and its constitutive element is form A: 20 yards of linen = 1 coat or x commodity A = y commodity B. The simple commodity form is therefore the germ of the money-form.

4. THE FETISHISM OF THE COMMODITY AND ITS SECRET

A commodity appears at first sight an extremely obvious, trivial thing. But its analysis brings out that it is a very strange thing, abounding in metaphysical subtleties and theological niceties. So far as it is a use-value, there is nothing mysterious about it, whether we consider it from the point of view that by its properties it satisfies human needs, or that it first takes on these properties as the product of human labour. It is absolutely clear that, by his activity, man changes the forms of the materials of nature in such a way as to make them useful to him. The form of wood, for instance, is altered if a table is made out of it. Nevertheless the table continues to be wood, an ordinary, sensuous thing. But as soon as it emerges as a commodity, it changes into a thing which transcends sensuousness. It not only stands with its feet on the ground, but, in relation to all other commodities, it stands on its head, and evolves out of its wooden brain grotesque ideas, far more wonderful than if it were to begin dancing of its own free will.[27]

The mystical character of the commodity does not therefore arise from its use-value. Just as little does it proceed from the nature of the determinants of value. For in the first place, however varied the useful kinds of labour, or productive activities, it is a physiological fact that they are functions of the human organism, and that each such function, whatever may be its nature or its form, is essentially the expenditure of human brain, nerves, muscles and sense organs. Secondly, with regard to the foundation of the quantitative determination of value, namely the duration of that expenditure or the quantity of labour, this is quite palpably different from its quality. In all situations, the labour-time it costs to produce the means of subsistence must necessarily concern mankind, although not to the same degree at different stages of development.[28] And finally, as soon as men start to work for each other in any way, their labour also assumes a social form.

Whence, then, arises the enigmatic character of the product of labour, as soon as it assumes the form of a commodity? Clearly, it arises from this form itself. The equality of the kinds of human labour takes on a physical form in the equal objectivity of the products of labour as values; the measure of the expenditure of human labour-power by its duration takes on the form of the magnitude of the value of the products of labour; and finally the relationships between the producers, within which the social characteristics of their labours are manifested, take on the form of a social relation between the products of labour.

The mysterious character of the commodity-form consists therefore simply in the fact that the commodity reflects the social characteristics of men's own labour as objective characteristics of the products of labour themselves, as the socio-natural properties of these things. Hence it also reflects the social relation of the producers to the sum total of labour as a social relation between objects, a relation which exists apart from and outside the producers. Through this substitution, the products of labour become commodities, sensuous things which are at the same time suprasensible or social. In the same way, the impression made by a thing on the optic nerve is perceived not as a subjective excitation of that nerve but as the objective form of a thing outside the eye. In the act of seeing, of course, light is really transmitted from one thing, the external object, to another thing, the eye. It is a physical relation between physical things. As against this, the commodity-form, and the value-relation of the products of labour within which it appears, have absolutely no connection with the physical nature of the commodity and the material [*dinglich*] relations arising out of this. It is nothing but the definite social relation between men themselves which assumes here, for them, the fantastic form of a relation between things. In order, therefore, to find an analogy we must take flight into the misty realm of religion. There the products of the human brain appear as autonomous figures endowed with a life of their own, which enter into relations both with each other and with the human race. So it is in the world of commodities with the products of men's hands. I call this the fetishism which attaches itself to the products of labour as soon as they are produced as commodities, and is therefore inseparable from the production of commodities.

---

[27] One may recall that China and the tables began to dance when the rest of the world appeared to be standing still – *pour encourager les autres*.*

[28] Among the ancient Germans the size of a piece of land was measured according to the labour of a day; hence the acre was called *Tagwerk, Tagwanne* (*jurnale*, or *terrajurnalis*, or *diornalis*), *Mannwerk, Mannskraft, Mannsmaad, Mannshauet*, etc. See Georg Ludwig von Maurer, *Einleitung zur Geschichte der Mark-, Hof-, usw. Verfassung*, Munich, 1854, p. 129 ff.

* 'To encourage the others'. A reference to the simultaneous emergence in the 1850s of the Taiping revolt in China and the craze for spiritualism which swept over upper-class German society. The rest of the world was 'standing still' in the period of reaction immediately after the defeat of the 1848 Revolutions.

As the foregoing analysis has already demonstrated, this fetishism of the world of commodities arises from the peculiar social character of the labour which produces them.

Objects of utility become commodities only because they are the products of the labour of private individuals who work independently of each other. The sum total of the labour of all these private individuals forms the aggregate labour of society. Since the producers do not come into social contact until they exchange the products of their labour, the specific social characteristics of their private labours appear only within this exchange. In other words, the labour of the private individual manifests itself as an element of the total labour of society only through the relations which the act of exchange establishes between the products, and, through their mediation, between the producers. To the producers, therefore, the social relations between their private labours appear as what they are, i.e. they do not appear as direct social relations between persons in their work, but rather as material [*dinglich*] relations between persons and social relations between things.

It is only by being exchanged that the products of labour acquire a socially uniform objectivity as values, which is distinct from their sensuously varied objectivity as articles of utility. This division of the product of labour into a useful thing and a thing possessing value appears in practice only when exchange has already acquired a sufficient extension and importance to allow useful things to be produced for the purpose of being exchanged, so that their character as values has already to be taken into consideration during production. From this moment on, the labour of the individual producer acquires a twofold social character. On the one hand, it must, as a definite useful kind of labour, satisfy a definite social need, and thus maintain its position as an element of the total labour, as a branch of the social division of labour, which originally sprang up spontaneously. On the other hand, it can satisfy the manifold needs of the individual producer himself only in so far as every particular kind of useful private labour can be exchanged with, i.e. counts as the equal of, every other kind of useful private labour. Equality in the full sense between different kinds of labour can be arrived at only if we abstract from their real inequality, if we reduce them to the characteristic they have in common, that of being the expenditure of human labour-power, of human labour in the abstract. The private producer's brain reflects this twofold social character of his labour only in the forms which appear in practical intercourse, in the exchange of products. Hence the socially useful character of his private labour is reflected in the form that the product of labour has to be useful to others, and the social character of the equality of the various kinds of labour is reflected in the form of the common character, as values, possessed by these materially different things, the products of labour.

Men do not therefore bring the products of their labour into relation with each other as values because they see these objects merely as the material integuments of homogeneous human labour. The reverse is true: by equating their different products to each other in exchange as values, they equate their different kinds of labour as human labour. They do this without being aware of it.[29] Value, therefore, does not have its description branded on its forehead; it rather transforms every product of labour into a social hieroglyphic. Later on, men try to decipher the hieroglyphic, to get behind the secret of their own social product: for the characteristic which objects of utility have of being values is as much men's social product as is their language. The belated scientific discovery that the products of labour, in so far as they are values, are merely the material expressions of the human labour expended to produce them, marks an epoch in the history of mankind's development, but by no means banishes the semblance of objectivity possessed by the social characteristics of labour. Something which is only valid for this particular form of production, the production of commodities, namely the fact that the specific social character of private labours carried on independently of each other consists in their equality as human labour, and, in the product, assumes the form of the existence of value, appears to those caught up in the relations of commodity production (and this is true both before and after the abovementioned scientific discovery) to be just as ultimately valid as the fact that the scientific dissection of the air into its component parts left the atmosphere itself unaltered in its physical configuration.

What initially concerns producers in practice when they make an exchange is how much of some other product they get for their own; in what proportions can the products be exchanged? As soon as these proportions have attained a certain customary stability, they appear to result from the nature of the products, so that, for instance, one ton of iron and two ounces of gold appear to be equal in value, in the same way as a pound of gold and a pound of iron are equal in weight, despite their different physical and chemical properties. The value character of the products of labour becomes firmly established only when they act as magnitudes of value. These magnitudes vary continually, independently of the will, foreknowledge and actions of the exchangers. Their own movement within society has for them the form of a movement made by things, and these things, far from being under their control, in fact control them. The production of commodities must be fully developed before the scientific conviction emerges, from experience itself, that all the different kinds of private labour (which are carried on independently of each other, and yet, as spontaneously developed branches of the social division of labour, are in a situation of all-round dependence on each other) are continually being reduced to the quantitative proportions in which society requires them. The reason for this reduction is that in the midst of the accidental and ever-fluctuating exchange relations between the products, the labour-time socially necessary to produce them asserts itself as a regulative law of nature. In the same way, the law of gravity asserts itself when a person's house collapses on top of him.[30] The determination of the magnitude of value by labour-time is therefore a secret hidden under the apparent movements in the relative values of commodities. Its discovery destroys the semblance of the merely accidental determination of the magnitude of the value of the products of labour, but by no means abolishes that determination's material form.

---

[29] Therefore, when Galiani said: Value is a relation between persons ('*La Ricchezza è una ragione tra due persone*') he ought to have added: a relation concealed beneath a material shell. (Galiani, *Della Moneta*, p. 221, Vol. 3 of Custodi's collection entitled *Scrittori classici italiani di economia politica, Parte moderna*, Milan, 1803.)

Reflection on the forms of human life, hence also scientific analysis of those forms, takes a course directly opposite to their real development. Reflection begins *post festum*,* and therefore with the results of the process of development ready to hand. The forms which stamp products as commodities and which are therefore the preliminary requirements for the circulation of commodities, already possess the fixed quality of natural forms of social life before man seeks to give an account, not of their historical character, for in his eyes they are immutable, but of their content and meaning. Consequently, it was solely the analysis of the prices of commodities which led to the determination of the magnitude of value, and solely the common expression of all commodities in money which led to the establishment of their character as values. It is however precisely this finished form of the world of commodities – the money form – which conceals the social character of private labour and the social relations between the individual

[30] 'What are we to think of a law which can only assert itself through periodic crises? It is just a natural law which depends on the lack of awareness of the people who undergo it' (Friedrich Engels, *Umrisse zu einer Kritik der Nationalökonomie*, in the *Deutsch-Französische Jahrbücher*, edited by Arnold Ruge and Karl Marx, Paris, 1844) [English translation in Marx/Engels' *Collected Works*, Vol. 3, London, 1975, p. 433].

---

* 'After the feast', i.e. after the events reflected on have taken place.

workers, by making those relations appear as relations between material objects, instead of revealing them plainly. If I state that coats or boots stand in a relation to linen because the latter is the universal incarnation of abstract human labour, the absurdity of the statement is self-evident. Nevertheless, when the producers of coats and boots bring these commodities into a relation with linen, or with gold or silver (and this makes no difference here), as the universal equivalent, the relation between their own private labour and the collective labour of society appears to them in exactly this absurd form.

The categories of bourgeois economics consist precisely of forms of this kind. They are forms of thought which are socially valid, and therefore objective, for the relations of production belonging to this historically determined mode of social production, i.e. commodity production. The whole mystery of commodities, all the magic and necromancy that surrounds the products of labour on the basis of commodity production, vanishes therefore as soon as we come to other forms of production.

As political economists are fond of Robinson Crusoe stories,[31] let us first look at Robinson on his island. Undemanding though he is by nature, he still has needs to satisfy, and must therefore perform useful labours of various kinds: he must make tools, knock together furniture, tame llamas, fish, hunt and so on. Of his prayers and the like, we take no account here, since our friend takes pleasure in them and sees them as recreation. Despite the diversity of his productive functions, he knows that they are only different forms of activity of one and the same Robinson, hence only different modes of human labour. Necessity itself compels him to divide his time with precision between his different functions. Whether one function occupies a greater space in his total activity than another depends on the magnitude of the difficulties to be overcome in attaining the useful effect aimed at. Our friend Robinson Crusoe learns this by experience, and having saved a watch, ledger, ink and pen from the shipwreck, he soon begins, like a good Englishman, to keep a set of books. His stock-book contains a catalogue of the useful objects he possesses, of the various operations necessary for their production, and finally of the labour-time that specific quantities of these products have on average cost him. All the relations between Robinson and these objects that form his self-created wealth are here so simple and transparent that even Mr Sedley Taylor* could understand them. And yet those relations contain all the essential determinants of value.

---

[31] Even Ricardo has his Robinson Crusoe stories. 'Ricardo makes his primitive fisherman and primitive hunter into owners of commodities who immediately exchange their fish and game in proportion to the labour-time which is materialized in these exchange-values. On this occasion he slips into the anachronism of allowing the primitive fisherman and hunter to calculate the value of their implements in accordance with the annuity tables used on the London Stock Exchange in 1817. Apart from bourgeois society, the "parallelograms of Mr Owen" seem to have been the only form of society Ricardo was acquainted with' *(Karl Marx, *Zur Kritik etc.*, pp. 38–9) [English translation, p. 60].

*The 'parallelograms' were the utopian socialist Robert Owen's suggestion for the most appropriate layout for a workers' settlement, made in *A New View of Society* (1813) and immediately seized on by his critics. Ricardo's reference to them is from his *On Protection of Agriculture*, London, 1822, p. 21.

Let us now transport ourselves from Robinson's island, bathed in light, to medieval Europe, shrouded in darkness. Here, instead of the independent man, we find everyone dependent – serfs and lords, vassals and suzerains, laymen and clerics. Personal dependence characterizes the social relations of material production as much as it does the other spheres of life based on that production. But precisely because relations of personal dependence form the given social foundation, there is no need for labour and its products to assume a fantastic form different from their reality. They take the shape, in the transactions of society, of services in kind and payments in kind. The natural form of labour, its particularity – and not, as in a society based on commodity production, its universality – is here its immediate social form. The *corvée* can be measured by time just as well as the labour which produces commodities, but every serf knows that what he expends in the service of his lord is a specific quantity of his own personal labour-power. The tithe owed to the priest is more clearly apparent than his blessing. Whatever we may think, then, of the different roles in which men confront each other in such a society, the social relations between individuals in the performance of their labour appear at all events as their own personal relations, and are not disguised as social relations between things, between the products of labour.

---

*The original German has here 'Herr M. Wirth', chosen by Marx as a run-of-the-mill vulgar economist and propagandist familiar to German readers. Engels introduced 'Mr Sedley Taylor', a Cambridge don against whom he polemicized in his preface to the fourth German edition (see above, p. 117).

For an example of labour in common, i.e. directly associated labour, we do not need to go back to the spontaneously developed form which we find at the threshold of the history of all civilized peoples.[32] We have one nearer to hand in the patriarchal rural industry of a peasant family which produces corn, cattle, yarn, linen and clothing for its own use. These things confront the family as so many products of its collective labour, but they do not confront each other as commodities. The different kinds of labour which create these products – such as tilling the fields, tending the cattle, spinning, weaving and making clothes – are already in their natural form social functions; for they are functions of the family, which, just as much as a society based on commodity production, possesses its own spontaneously developed division of labour. The distribution of labour within the family and the labour-time expended by the individual members of the family, are regulated by differences of sex and age as well as by seasonal variations in the natural conditions of labour. The fact that the expenditure of the individual labour-powers is measured by duration appears here, by its very nature, as a social characteristic of labour itself, because the individual labour-powers, by their very nature, act only as instruments of the joint labour-power of the family.

Let us finally imagine, for a change, an association of free men, working with the means of production held in common, and expending their many different forms of labour-power in full self-awareness as one single social labour force. All the characteristics of Robinson's labour are repeated here, but with the difference that they are social instead of individual. All Robinson's products were exclusively the result of his own personal labour and they were therefore directly objects of utility for him personally. The total product of our imagined association is a social product. One part of this product serves as fresh means of production and remains social. But another part is consumed by the members of the association as means of subsistence. This part must therefore be divided amongst them. The way this division is made will vary with the particular kind of social organization of production and the corresponding level of social development attained by the producers. We shall assume, but only for the sake of a parallel with the production of commodities, that the share of each individual producer in the means of subsistence is determined by his labour-time. Labour-time would in that case play a double part. Its apportionment in accordance with a definite social plan maintains the correct proportion between the different functions of labour and the various needs of the associations. On the other hand, labour-time also serves as a measure of the part taken by each individual in the common labour, and of his share in the part of the total product destined for individual consumption. The social relations of the individual producers, both towards their labour and the products of their labour, are here transparent in their simplicity, in production as well as in distribution.

---

[32] 'A ridiculous notion has spread abroad recently that communal property in its natural, spontaneous form is specifically Slav, indeed exclusively Russian. In fact, it is the primitive form that we can prove to have existed among Romans, Teutons and Celts, and which indeed still exists to this day in India, in a whole range of diverse patterns, albeit sometimes only as remnants. A more exact study of the Asiatic, and specifically of the Indian form of communal property would indicate the way in which different forms of spontaneous, primitive communal property give rise to different forms of its dissolution. Thus the different original types of Roman and Germanic private property can be deduced from the different forms of Indian communal property' (Karl Marx, *Zur Kritik, etc.*, p. 10) [English translation, p. 33].

For a society of commodity producers, whose general social relation of production consists in the fact that they treat their products as commodities, hence as values, and in this material [*sachlich*] form bring their individual, private labours into relation with each other as homogeneous human labour, Christianity with its religious cult of man in the abstract, more particularly in its bourgeois development, i.e. in Protestantism, Deism, etc., is the most fitting form of religion. In the ancient Asiatic, Classical-antique, and other such modes of production, the transformation of the product into a commodity, and therefore men's existence as producers of commodities, plays a subordinate role, which however increases in importance as these communities approach nearer and nearer to the stage of their dissolution. Trading nations, properly so called, exist only in the interstices of the ancient world, like the gods of Epicurus in the *intermundia*,* or Jews in the pores of Polish society. Those ancient social organisms of production are much more simple and transparent than those of bourgeois society.

*According to the Greek philosopher Epicurus (*c.* 341–*c.* 270 B.C.), the gods existed only in the *intermundia*, or spaces between different worlds, and had no influence on the course of human affairs. Very few of the writings of Epicurus have been preserved in the original Greek, and this particular idea survived only by being included in Cicero, *De natura deorum*, Book I, Section 18.

But they are founded either on the immaturity of man as an individual, when he has not yet torn himself loose from the umbilical cord of his natural species-connection with other men, or on direct relations of dominance and servitude. They are conditioned by a low stage of development of the productive powers of labour and correspondingly limited relations between men within the process of creating and reproducing their material life, hence also limited relations between man and nature. These real limitations are reflected in the ancient worship of nature, and in other elements of tribal religions. The religious reflections of the real world can, in any case, vanish only when the practical relations of everyday life between man and man, and man and nature, generally present themselves to him in a transparent and rational form. The veil is not removed from the countenance of the social life-process, i.e. the process of material production, until it becomes production by freely associated men, and stands under their conscious and planned control. This, however, requires that society possess a material foundation, or a series of material conditions of existence, which in their turn are the natural and spontaneous product of a long and tormented historical development.

Political economy has indeed analysed value and its magnitude, however incompletely,[33] and has uncovered the content concealed within these forms. But it has never once asked the question why this content has assumed that particular form, that is to say, why labour is expressed in value, and why the measurement of labour by its duration is expressed in the magnitude of the value of the product.[34] These formulas, which bear the unmistakable stamp of

---

[33] The insufficiency of Ricardo's analysis of the magnitude of value – and his analysis is by far the best – will appear from the third and fourth books of this work.* As regards value in general, classical political economy in fact nowhere distinguishes explicitly and with a clear awareness between labour as it appears in the value of a product, and the same labour as it appears in the product's use-value. Of course the distinction is made in practice, since labour is treated sometimes from its quantitative aspect, and at other times qualitatively. But it does not occur to the economists that a purely quantitative distinction between the kinds of labour presupposes their qualitative unity or equality, and therefore their reduction to abstract human labour. For instance, Ricardo declares that he agrees with Destutt de Tracy when the latter says: 'As it is certain that our physical and moral faculties are alone our original riches, the employment of those faculties, labour of some kind, is our original treasure, and it is always from this employment that all those things are created which we call riches . . . It is certain too, that all those things only represent the labour which has created them, and if they have a value, or even two distinct values, they can only derive them from that' (the value) 'of the labour from which they emanate' (Ricardo, *The Principles of Political Economy*, 3rd edn, London, 1821, p. 334).† We would here only point out that

*These are the books that appeared, respectively, as Volume 3 of *Capital*, and *Theories of Surplus-Value* (3 volumes).

†Destutt de Tracy, *Élémens d'idéologie*, Parts 4 and 5, Paris, 1826, pp. 35–6.

Ricardo imposes his own more profound interpretation on the words of Destutt. Admittedly Destutt does say that all things which constitute wealth 'represent the labour which has created them', but, on the other hand, he also says that they acquire their 'two different values' (use-value and exchange-value) from 'the value of labour'. He thus falls into the commonplace error of the vulgar economists, who assume the value of one commodity (here labour) in order in turn to use it to determine the values of other commodities. But Ricardo reads him as if he had said that labour (not the value of labour) is represented both in use-value and in exchange-value. Nevertheless, Ricardo himself makes so little of the dual character of the labour represented in this twofold way that he is forced to spend the whole of his chapter 'Value and Riches, their Distinctive Properties' on a laborious examination of the trivialities of a J. B. Say. And at the end he is therefore quite astonished to find that while Destutt agrees with him that labour is the source of value, he nevertheless also agrees with Say about the concept of value.*

[34] It is one of the chief failings of classical political economy that it has never succeeded, by means of its analysis of commodities, and in particular of their value, in discovering the form of value which in fact turns value into exchange-value. Even its best representatives, Adam Smith and Ricardo, treat the form of value as something of indifference, something external to the nature of the commodity itself. The explanation for this is not simply that their attention is entirely absorbed by the analysis of the magnitude of value. It lies deeper. The value-form of the product of labour is the most abstract, but also the most universal form of the bourgeois mode of production; by that fact it stamps the bourgeois mode of production as a particular kind of social production of a historical and transitory character. If then we make the mistake of treating it as the eternal natural form of social production, we necessarily overlook the specificity of the value-form, and consequently of the commodity-form together with its further developments, the money form, the capital form, etc. We therefore find that economists who are entirely agreed that labour-time is the measure of the magnitude of value, have the strangest and most contradictory ideas about money, that is, about the universal equivalent in its finished form. This emerges sharply when they deal with banking, where the commonplace definitions of money will no longer hold water. Hence there has arisen in opposition to the classical economists a restored Mercantilist System (Ganilh etc.), which sees in value only the social form, or rather its insubstantial semblance. Let me point out once and for all that by classical political economy I mean all the economists who, since the time of W. Petty, have investigated the real internal framework [*Zusammenhang*] of bourgeois

* 'I am sorry to be obliged to add that M. de Tracy supports, by his authority, the definitions which M. Say has given of the words "value", "riches", and "utility" ' (Ricardo, op. cit., p. 334).

belonging to a social formation in which the process of production has mastery over man, instead of the opposite, appear to the political economists' bourgeois consciousness to be as much a self-evident and nature-imposed necessity as productive labour itself. Hence the pre-bourgeois forms of the social organization of production are treated by political economy in much the same way as the Fathers of the Church treated pre-Christian religions.[35]

---

relations of production, as opposed to the vulgar economists who only flounder around within the apparent framework of those relations, ceaselessly ruminate on the materials long since provided by scientific political economy, and seek there plausible explanations of the crudest phenomena for the domestic purposes of the bourgeoisie. Apart from this, the vulgar economists confine themselves to systematizing in a pedantic way, and proclaiming for everlasting truths, the banal and complacent notions held by the bourgeois agents of production about their own world, which is to them the best possible one.

[35] 'The economists have a singular way of proceeding. For them, there are only two kinds of institutions, artificial and natural. The institutions of feudalism are artificial institutions, those of the bourgeoisie are natural institutions. In this they resemble the theologians, who likewise establish two kinds of religion. Every religion which is not heirs is an invention of men, while their own is an emanation of God . . . Thus there has been history, but there is no longer any' (Karl Marx, *Misère de la philosophie. Réponse à la philosophie de la misère de M. Proudhon*, 1847, p. 113).* Truly comical is M. Bastiat, who imagines that the ancient Greeks and Romans lived by plunder alone. For if people live by plunder for centuries there must, after all, always be something there to plunder; in other words, the objects of plunder must be continually reproduced. It seems, therefore, that even the Greeks and the Romans had a process of production, hence an economy, which constituted the material basis of their world as much as the bourgeois economy constitutes that of the present-day world. Or perhaps Bastiat means that a mode of production based on the labour of slaves is based on a system of plunder? In that case he is on dangerous ground. If a giant thinker like Aristotle could err in his evaluation of slave-labour, why should a dwarf economist like Bastiat be right in his evaluation of wage-labour? I seize this opportunity of briefly refuting an objection made by a German–American publication to my work *Zur Kritik der Politischen Ökonomie*, 1859. My view is that each particular mode of production, and the relations of production corresponding to it at each given moment, in short 'the economic structure of society', is 'the real foundation, on which arises a legal and political superstructure and to which correspond definite forms of social consciousness', and that 'the mode of production of material life conditions the general process of social, political and intellectual life'.†

*English translation: Karl Marx, *The Poverty of Philosophy*, London, 1966, p. 105.

†These passages are taken from the Preface to *A Contribution to the Critique of Political Economy*, written in January 1859 (English translation, pp. 20–21).

The degree to which some economists are misled by the fetishism attached to the world of commodities, or by the objective appearance of the social characteristics of labour, is shown, among other things, by the dull and tedious dispute over the part played by nature in the formation of exchange-value. Since exchange-value is a definite social manner of expressing the labour bestowed on a thing, it can have no more natural content than has, for example, the rate of exchange.

As the commodity-form is the most general and the most undeveloped form of bourgeois production, it makes its appearance at an early date, though not in the same predominant and therefore characteristic manner as nowadays. Hence its fetish character is still relatively easy to penetrate. But when we come to more concrete forms, even this appearance of simplicity vanishes. Where did the illusions of the Monetary System come from? The adherents of the Monetary System did not see gold and silver as representing money as a social relation of production, but in the form of natural objects with peculiar social properties. And what of modern political economy, which looks down so disdainfully on the Monetary System? Does not its fetishism become quite palpable when it deals with capital? How long is it since the disappearance of the Physiocratic illusion that ground rent grows out of the soil, not out of society?

But, to avoid anticipating, we will content ourselves here with one more example relating to the commodity-form itself. If commodities could speak, they would say this: our use-value may interest men, but it does not belong to us as objects. What does belong to us as objects, however, is our value. Our own inter-

---

In the opinion of the German–American publication this is all very true for our own times, in which material interests are preponderant, but not for the Middle Ages, dominated by Catholicism, nor for Athens and Rome, dominated by politics. In the first place, it strikes us as odd that anyone should suppose that these well-worn phrases about the Middle Ages and the ancient world were unknown to anyone else. One thing is clear: the Middle Ages could not live on Catholicism, nor could the ancient world on politics. On the contrary, it is the manner in which they gained their livelihood which explains why in one case politics, in the other case Catholicism, played the chief part. For the rest, one needs no more than a slight acquaintance with, for example, the history of the Roman Republic, to be aware that its secret history is the history of landed property. And then there is Don Quixote, who long ago paid the penalty for wrongly imagining that knight errantry was compatible with all economic forms of society.

course as commodities proves it. We relate to each other merely as exchange-values. Now listen how those commodities speak through the mouth of the economist:

'Value (i.e. exchange-value) is a property of things, riches (i.e. use-value) of man. Value, in this sense, necessarily implies exchanges, riches do not.'[36]

'Riches (use-value) are the attribute of man, value is the attribute of commodities. A man or a community is rich, a pearl or a diamond is valuable... A pearl or a diamond is valuable as a pearl or diamond.'[37]

So far no chemist has ever discovered exchange-value either in a pearl or a diamond. The economists who have discovered this chemical substance, and who lay special claim to critical acumen, nevertheless find that the use-value of material objects belongs to them independently of their material properties, while their value, on the other hand, forms a part of them as objects. What confirms them in this view is the peculiar circumstance that the use-value of a thing is realized without exchange, i.e. in the direct relation between the thing and man, while, inversely, its value is realized only in exchange, i.e. in a social process. Who would not call to mind at this point the advice given by the good Dogberry to the night-watchman Seacoal?*

'To be a well-favoured man is the gift of fortune; but reading and writing comes by nature.'[38]

[36] *Observations on Some Verbal Disputes in Pol. Econ., Particularly Relating to Value, and to Supply and Demand*, London, 1821, p. 16.

[37] S. Bailey, op. cit., p. 165.

[38] Both the author of *Observations etc.*, and S. Bailey accuse Ricardo of converting exchange-value from something relative into something absolute. The reverse is true. He has reduced the apparent relativity which these things (diamonds, pearls, etc.) possess to the true relation hidden behind the appearance, namely their relativity as mere expressions of human labour. If the followers of Ricardo answer Bailey somewhat rudely, but by no means convincingly, this is because they are unable to find in Ricardo's own works any elucidation of the inner connection between value and the form of value, or exchange-value.

---

* In Shakespeare's comedy *Much Ado About Nothing*, Act 3, Scene 3.

Chapter 2: The Process of Exchange

Commodities cannot themselves go to market and perform exchanges in their own right. We must, therefore, have recourse to their guardians, who are the possessors of commodities. Commodities are things, and therefore lack the power to resist man. If they are unwilling, he can use force; in other words, he can take possession of them.[1] In order that these objects may enter into relation with each other as commodities, their guardians must place themselves in relation to one another as persons whose will resides in those objects, and must behave in such a way that each does not appropriate the commodity of the other, and alienate his own, except through an act to which both parties consent. The guardians must therefore recognize each other as owners of private property. This juridical relation, whose form is the contract, whether as part of a developed legal system or not, is a relation between two wills which mirrors the economic relation. The content of this juridical relation (or relation of two wills) is itself determined by the economic relation.[2] Here the persons exist for one another merely as representatives and hence owners, of commodities. As we proceed to develop our investigation, we shall find, in general, that the characters who appear on the economic stage are merely personifications of economic relations; it is as the bearers* of these economic relations that they come into contact with each other.

---

[1] In the twelfth century, so renowned for its piety, very delicate things often appear among these commodities. Thus a French poet of the period enumerates among the commodities to be found in the fair of Lendit, alongside clothing, shoes, leather, implements of cultivation, skins, etc., also *'femmes folles de leur corps'*.*

[2] Proudhon creates his ideal of justice, of *'justice éternelle'*, from the juridical relations that correspond to the production of commodities: he thereby proves, to the consolation of all good petty bourgeois, that the production of commodities is a form as eternal as justice. Then he turns round and seeks to reform the actual production of commodities, and the corresponding legal system, in accordance with this ideal. What would one think of a chemist who, instead of studying the actual laws governing molecular interactions, and on that basis solving definite problems, claimed to regulate

* 'Wanton women'. This passage comes from the *Dit du Lendit*, a satirical poem by the medieval French poet Guillot de Paris.

What chiefly distinguishes a commodity from its owner is the fact that every other commodity counts for it only as the form of appearance of its own value. A born leveller and cynic, it is always ready to exchange not only soul, but body, with each and every other commodity, be it more repulsive than Maritornes herself.† The owner makes up for this lack in the commodity of a sense of the concrete, physical body of the other commodity, by his own five and more senses. For the owner, his commodity possesses no direct use-value. Otherwise, he would not bring it to market. It has use-value for others; but for himself its only direct use-value is as a bearer of exchange-value, and consequently, a means of exchange.[3] He therefore makes up his mind to sell it in return for commodities whose use-value is of service to him. All commodities are non-use-values for their owners, and use-values for their non-owners. Consequently, they must all change hands. But this changing of hands constitutes their exchange, and their exchange puts them in relation with each other as values and realizes them as values. Hence commodities must be realized as values before they can be realized as use-values.

On the other hand, they must stand the test as use-values before they can be realized as values. For the labour expended on them only counts in so far as it is expended in a form which is useful

---

those interactions by means of the 'eternal ideas' of '*naturalité*' and '*affinité*'? Do we really know any more about 'usury', when we say it contradicts '*justice éternelle*', '*équité éternelle*', '*mutualité éternelle*', and other '*vérités éternelles*' than the fathers of the church did when they said it was incompatible with '*grâce éternelle*', '*foi éternelle*', and '*la volunté éternelle de Dieu*'?

[3] 'For twofold is the use of every object ... The one is peculiar to the object as such, the other is not, as a sandal which may be worn and is also exchangeable. Both are uses of the sandal, for even he who exchanges the sandal for the money or food he is in need of, makes use of the sandal as a sandal. But not in its natural way. For it has not been made for the sake of being exchanged' (Aristotle, *Republic*, I, i, c. 9).

---

*The concept of an object (or person) as the receptacle, repository, bearer [*Träger*] of some thing or tendency quite different from it appears repeatedly in *Capital*, and I have tried to translate it uniformly as 'bearer'.

†Maritornes: a character from Cervantes' novel *Don Quixote*.

for others. However, only the act of exchange can prove whether that labour is useful for others, and its product consequently capable of satisfying the needs of others.

The owner of a commodity is prepared to part with it only in return for other commodities whose use-value satisfies his own need. So far, exchange is merely an individual process for him. On the other hand, he desires to realize his commodity, as a value, in any other suitable commodity of the same value. It does not matter to him whether his own commodity has any use-value for the owner of the other commodity or not. From this point of view, exchange is for him a general social process. But the same process cannot be simultaneously for all owners of commodities both exclusively individual and exclusively social and general.

Let us look at the matter a little more closely. To the owner of a commodity, every other commodity counts as the particular equivalent of his own commodity. Hence his own commodity is the universal equivalent for all the others. But since this applies to every owner, there is in fact no commodity acting as universal equivalent, and the commodities possess no general relative form of value under which they can be equated as values and have the magnitude of their values compared. Therefore they definitely do not confront each other as commodities, but as products or use-values only.

In their difficulties our commodity-owners think like Faust: 'In the beginning was the deed.'* They have therefore already acted before thinking. The natural laws of the commodity have manifested themselves in the natural instinct of the owners of commodities. They can only bring their commodities into relation as values, and therefore as commodities, by bringing them into an opposing relation with some one other commodity, which serves as the universal equivalent. We have already reached that result by our analysis of the commodity. But only the action of society can turn a particular commodity into the universal equivalent. The social action of all other commodities, therefore, sets apart the particular commodity in which they all represent their values. The natural form of this commodity thereby becomes the socially recognized equivalent form. Through the agency of the social process it becomes the specific social function of the commodity

---

*'*Im Anfang war die Tat*' (Goethe, *Faust*, Part I, Scene 3, Faust's Study, line 1237).

which has been set apart to be the universal equivalent. It thus becomes – money.

'*Illi unum consilium habent et virtutem et potestatem suam bestiae tradunt . . . Et ne quis possit emere aut vendere, nisi qui habet characterem aut nomen bestiae, aut numerum nominis eius*' (Apocalypse).*

Money necessarily crystallizes out of the process of exchange, in which different products of labour are in fact equated with each other, and thus converted into commodities. The historical broadening and deepening of the phenomenon of exchange develops the opposition between use-value and value which is latent in the nature of the commodity. The need to give an external expression to this opposition for the purposes of commercial intercourse produces the drive towards an independent form of value, which finds neither rest nor peace until an independent form has been achieved by the differentiation of commodities into commodities and money. At the same rate, then, as the transformation of the products of labour into commodities is accomplished, one particular commodity is transformed into money.[4]

The direct exchange of products has the form of the simple expression of value in one respect, but not as yet in another. That form was x commodity A $= y$ commodity B. The form of the direct exchange of products is x use-value A $= y$ use-value B.[5] The articles A and B in this case are not as yet commodities, but become so only through the act of exchange. The first way in which

[4] From this we may form an estimate of the craftiness of petty-bourgeois socialism, which wants to perpetuate the production of commodities while simultaneously abolishing the 'antagonism between money and commodities', i.e. abolishing money itself, since money only exists in and through this antagonism.* One might just as well abolish the Pope while leaving Catholicism in existence. For more on this point see my work *Zur Kritik der Politischen Ökonomie*, p. 61 ff. [English translation, pp. 83–6].

[5] So long as a chaotic mass of articles is offered as the equivalent for a single article (as is often the case among savages), instead of two distinct objects of utility being exchanged, we are only at the threshold of even the direct exchange of products.

* This is directed at the proposal of John Gray, in *The Social System* (1831), for the introduction of labour-money, later taken up by Proudhon.

* 'These have one mind, and shall give their power and strength unto the beast' (Revelation 17: 13). 'And that no man might buy or sell, save that he had the mark, or the name of the beast, or the number of his name' (Revelation 13: 17).

an object of utility attains the possibility of becoming an exchange-value is to exist as a non-use-value, as a quantum of use-value superfluous to the immediate needs of its owner. Things are in themselves external to man, and therefore alienable. In order that this alienation [*Veräusserung*] may be reciprocal, it is only necessary for men to agree tacitly to treat each other as the private owners of those alienable things, and, precisely for that reason, as persons who are independent of each other. But this relationship of reciprocal isolation and foreignness does not exist for the members of a primitive community of natural origin, whether it takes the form of a patriarchal family, an ancient Indian commune or an Inca state. The exchange of commodities begins where communities have their boundaries, at their points of contact with other communities, or with members of the latter. However, as soon as products have become commodities in the external relations of a community, they also, by reaction, become commodities in the internal life of the community. Their quantitative exchange-relation is at first determined purely by chance. They become exchangeable through the mutual desire of their owners to alienate them. In the meantime, the need for others' objects of utility gradually establishes itself. The constant repetition of exchange makes it a normal social process. In the course of time, therefore, at least some part of the products must be produced intentionally for the purpose of exchange. From that moment the distinction between the usefulness of things for direct consumption and their usefulness in exchange becomes firmly established. Their use-value becomes distinguished from their exchange-value. On the other hand, the quantitative proportion in which the things are exchangeable becomes dependent on their production itself. Custom fixes their values at definite magnitudes.

In the direct exchange of products, each commodity is a direct means of exchange to its owner, and an equivalent to those who do not possess it, although only in so far as it has use-value for them. At this stage, therefore, the articles exchanged do not acquire a value-form independent of their own use-value, or of the individual needs of the exchangers. The need for this form first develops with the increase in the number and variety of the commodities entering into the process of exchange. The problem and the means for its solution arise simultaneously. Commercial intercourse, in which the owners of commodities exchange and compare their own articles with various other articles, never takes place unless different kinds of commodities belonging to different owners are exchanged for, and equated as values with, one single further kind of commodity. This further commodity, by becoming the equivalent of various other commodities, directly acquires the form of a universal or social equivalent, if only within narrow limits. The universal equivalent form comes and goes with the momentary social contacts which call it into existence. It is transiently attached to this or that commodity in alternation. But with the development of exchange it fixes itself firmly and exclusively onto particular kinds of commodity, i.e. it crystallizes out into the money-form. The particular kind of commodity to which it sticks is at first a matter of accident. Nevertheless there are two circumstances which are by and large decisive. The money-form comes to be attached either to the most important articles of exchange from outside, which are in fact the primitive and spontaneous forms of manifestation of the exchange-value of local products, or to the object of utility which forms the chief element of indigenous alienable wealth, for example cattle. Nomadic peoples are the first to develop the money-form, because all their worldly possessions are in a movable and therefore directly alienable form, and because their mode of life, by continually bringing them into contact with foreign communities, encourages the exchange of products. Men have often made man himself into the primitive material of money, in the shape of the slave, but they have never done this with the land and soil. Such an idea could only arise in a bourgeois society, and one which was already well developed. It dates from the last third of the seventeenth century, and the first attempt to implement the idea on a national scale was made a century later, during the French bourgeois revolution.*

In the same proportion as exchange bursts its local bonds, and the value of commodities accordingly expands more and more into the material embodiment of human labour as such, in that proportion does the money-form become transferred to commodities which are by nature fitted to perform the social function of a universal equivalent. Those commodities are the precious metals.

The truth of the statement that 'although gold and silver are not by nature money, money is by nature gold and silver',[6] is

[6] Karl Marx, op. cit., p. 135 [English translation, p. 155]. 'The metals . . . are by their nature money' (Galiani, *Della Moneta*, in Custodi's collection, *Parte moderna*, Vol. 3, p. 137).

---

*The issue of the *assignats* in 1789, backed by confiscated Church lands.

shown by the appropriateness of their natural properties for the functions of money.[7] So far, however, we are acquainted with only one function of money, namely to serve as the form of appearance of the value of commodities, that is as the material in which the magnitudes of their values are socially expressed. Only a material whose every sample possesses the same uniform quality can be an adequate form of appearance of value, that is a material embodiment of abstract and therefore equal human labour. On the other hand, since the difference between the magnitudes of value is purely quantitative, the money commodity must be capable of purely quantitative differentiation, it must therefore be divisible at will, and it must also be possible to assemble it again from its component parts. Gold and silver possess these properties by nature.

The money commodity acquires a dual use-value. Alongside its special use-value as a commodity (gold, for instance, serves to fill hollow teeth, it forms the raw material for luxury articles, etc.) it acquires a formal use-value, arising out of its specific social function.

Since all other commodities are merely particular equivalents for money, the latter being their universal equivalent, they relate to money as particular commodities relate to the universal commodity.[8]

We have seen that the money-form is merely the reflection thrown upon a single commodity by the relations between all other commodities. That money is a commodity[9] is therefore only a discovery for those who proceed from its finished shape in order to analyse it afterwards. The process of exchange gives to the commodity which it has converted into money not its value but its specific value-form. Confusion between these two attributes has misled some writers into maintaining that the value of gold and silver is imaginary.[10] The fact that money can, in certain functions, be replaced by mere symbols of itself, gave rise to another mistaken notion, that it is itself a mere symbol. Nevertheless, this error did contain the suspicion that the money-form of the thing is external to the thing itself, being simply the form of appearance of human relations hidden behind it. In this sense every commodity is a symbol, since, as value, it is only the material shell of the human labour expended on it.[11] But if it is declared that the social characteristics assumed by material objects, or the material characteristics assumed by the social determinations of labour on the basis of a definite mode of production, are mere symbols, then it is also declared, at the same time, that these characteristics are the arbitrary product of human reflection. This was the kind of explanation favoured by the eighteenth century: in this way the Enlightenment endeavoured, at least temporarily, to remove the appearance of strangeness from the mysterious shapes assumed by human relations whose origins they were unable to decipher.

[7] For further details on this subject see the chapter on 'The Precious Metals' in my work cited above [English translation, pp. 153–7].

[8] 'Money is the universal commodity' (Verri, op. cit., p. 16).

[9] 'Silver and gold themselves, which we may call by the general name of Bullion, are . . . commodities . . . rising and falling in . . . value . . . Bullion then may be reckoned to be of higher value, where the smaller weight will purchase the greater quantity of the product or manufacture of the country etc.' (S. Clement, *A Discourse of the General Notions of Money, Trade, and Exchange, as They Stand in Relations to Each Other. By a Merchant*, London, 1695, p. 7). 'Silver and gold, coined or uncoined, tho' they are used for a measure of all other things, are no less a commodity than wine, oyl, tobacco, cloth or stuffs' (J. Child, *A Discourse Concerning Trade, and That in Particular of the East-Indies etc.*, London, 1689, p. 2). 'The stock and riches of the kingdom cannot properly be confined to money, nor ought gold and silver to be excluded from being merchandize' (T. Papillon, *The East-India Trade a Most Profitable Trade*, London, 1677, p. 4).

---

[10] 'Gold and silver have value as metals before they are money' (Galiani, op. cit., p. 72). Locke says, 'The universal consent of mankind gave to silver, on account of its qualities which made it suitable for money, an imaginary value' (John Locke, *Some Considerations etc.*, 1691, in *Works*, ed. 1777, Vol. 2, p. 15). Law, on the other hand, says 'How could different nations give an imaginary value to any single thing ... or how could this imaginary value have maintained itself?' But he himself understood very little of the matter, for example 'Silver was exchanged in proportion to the use-value it possessed, consequently in proportion to its real value. By its adoption as money it received an additional value (*une valeur additionnelle*)' (Jean Law, *Considérations sur le numéraire et le commerce*, in E. Daire's edition of *Économistes financiers du XVIII siècle*, pp. 469–70).

[11] 'Money is their (the commodities') symbol' (V. de Forbonnais, *Élémens du commerce*, new edn, Leyden, 1776, Vol. 2, p. 143). 'As a symbol it is attracted by the commodities' (ibid. p. 155). 'Money is a symbol of a thing and represents it' (Montesquieu, *Esprit des lois*, *Œuvres*, London, 1767, Vol. 2, p. 3). 'Money is not a mere symbol, for it is itself wealth; it does not represent the values, it is their equivalent' (Le Trosne, op. cit., p. 910). 'If we consider the concept of value, we must look on the thing itself only as a symbol; it counts not as itself, but as what it is worth' (Hegel, op. cit., p. 100).* Long before the economists, lawyers made fashionable the idea that money is a mere symbol, and that the value of the precious metals is purely imaginary. This they did in the sycophantic service of the royal power, supporting the right of the latter to debase the coinage, during the whole of the Middle Ages, by the traditions of the Roman Empire and the conceptions of money to be found in the Digest. 'Let no one call into question,' says their apt pupil, Philip of Valois, in a decree of 1346, 'that the trade, the composition, the supply, and the power of issuing ordinances on the currency ... belongs exclusively to us and to our royal majesty, to fix such a rate and at such a price as it shall please us and seem good to us.' It was a maxim of Roman Law that the value of money was fixed by Imperial decree. It was expressly forbidden to treat money as a commodity. '*Pecunias vero nulli emere fas erit, nam in usu publico constitutas*

*This is a reference to the *Philosophy of Right*, para. 63, Addition (English translation, p. 240).

It has already been remarked above that the equivalent form of a commodity does not imply that the magnitude of its value can be determined. Therefore, even if we know that gold is money, and consequently directly exchangeable with all other commodities, this still does not tell us how much 10lb. of gold is worth, for instance. Money, like every other commodity, cannot express the magnitude of its value except relatively in other commodities. This value is determined by the labour-time required for its production, and is expressed in the quantity of any other commodity in which the same amount of labour-time is congealed.[12] This establishing of its relative value occurs at the source of its production by means of barter. As soon as it enters into circulation as money, its value is already given. In the last decades of the seventeenth century the first step in the analysis of money, the discovery that money is a commodity, had already been taken; but this was merely the first step, and nothing more. The difficulty lies not in comprehending that money is a commodity, but in discovering how, why and by what means a commodity becomes money.[13]

---

oportet non esse mercem.'* There is a good discussion of this by G. F. Pagnini, in *Saggio sopra il giusto pregio delle cose*, 1751, printed in Custodi's collection, *Parte moderna*, Vol. 2. In the second part of his work Pagnini directs his polemic especially against the legal gentlemen.

[12] 'If a man can bring to London an ounce of silver out of the Earth of Peru, in the same time that he can produce a bushel of corn, then the one is the natural price of the other: now, if by reason of new or more easie mines a man can procure two ounces of silver as easily as he formerly did one, the corn will be as cheap at ten shillings the bushel as it was before at five shillings, *caeteris paribus*' (William Petty, *A Treatise of Taxes and Contributions*, London, 1667, p. 32).

[13] The learned Professor Roscher, after first informing us that 'the false definitions of money may be divided into two main groups: those which make

*'However, it shall not be lawful for anyone to buy money, for, as it was created for public use, it is not permissible for it to be a commodity' (*Codex Theodosianus*, lib. 9, tit. 23).

We have already seen, from the simplest expression of value, x commodity A $= y$ commodity B, that the thing in which the magnitude of the value of another thing is represented appears to have the equivalent form independently of this relation, as a social property inherent in its nature. We followed the process by which this false semblance became firmly established, a process which was completed when the universal equivalent form became identified with the natural form of a particular commodity, and thus crystallized into the money-form. What appears to happen is not that a particular commodity becomes money because all other commodities express their values in it, but, on the contrary, that all other commodities universally express their values in a particular commodity because it is money. The movement through which this process has been mediated vanishes in its own result, leaving no trace behind. Without any initiative on their part, the commodities find their own value-configuration ready to hand, in the form of a physical commodity existing outside but also alongside them. This physical object, gold or silver in its crude state, becomes, immediately on its emergence from the bowels of the earth, the direct incarnation of all human labour. Hence the magic of money. Men are henceforth related to each other in their social process of production in a purely atomistic way. Their own relations of production therefore assume a material shape which is independent of their control and their conscious individual action. This situation is manifested first by the fact that the products of men's labour universally take on the form of commodities. The riddle of the money fetish is therefore the riddle of the commodity fetish, now become visible and dazzling to our eyes.

---

it more, and those which make it less, than a commodity', gives us a motley catalogue of works on the nature of money, which does not provide even the glimmer of an insight into the real history of the theory. He then draws this moral: 'For the rest, it is not to be denied that most of the later economists do not bear sufficiently in mind the peculiarities that distinguish money from other commodities' (it is then, after all, either more or less than a commodity!) . . . 'So far, the semi-mercantilist reaction of Ganilh is not altogether without foundation' (Wilhelm Roscher, *Die Grundlagen der Nationalökonomie*, 3rd edn, 1858, pp. 207–10). More! Less! Not sufficiently! So far! Not altogether! What a way of determining one's concepts! And this eclectic professorial twaddle is modestly baptized by Herr Roscher 'the anatomico-physiological method' of political economy! However, he does deserve credit for one discovery, namely, that money is 'a pleasant commodity'.

Chapter 3: Money, or the Circulation of Commodities

I. THE MEASURE OF VALUES

Throughout this work I assume that gold is the money commodity, for the sake of simplicity.

The first main function of gold is to supply commodities with the material for the expression of their values, or to represent their values as magnitudes of the same denomination, qualitatively equal and quantitatively comparable. It thus acts as a universal measure of value, and only through performing this function does gold, the specific equivalent commodity, become money.

It is not money that renders the commodities commensurable. Quite the contrary. Because all commodities, as values, are objectified human labour, and therefore in themselves commensurable, their values can be communally measured in one and the same specific commodity, and this commodity can be converted into the common measure of their values, that is into money. Money as a measure of value is the necessary form of appearance of the measure of value which is immanent in commodities, namely labour-time.[1]

---

[1] The question why money does not itself directly represent labour-time, so that a piece of paper may represent, for instance, x hours' labour, comes down simply to the question why, on the basis of commodity production, the products of labour must take the form of commodities. This is obvious, because their taking the form of commodities implies their differentiation into commodities [on the one hand] and the money commodity [on the other]. It is also asked why private labour cannot be treated as its opposite, directly social labour. I have elsewhere discussed exhaustively the shallow utopianism of the idea of 'labour-money' in a society founded on the production of commodities (op. cit., p. 61 ff.).* On this point I will only say further that Owen's 'labour money', for instance, is no more 'money' than a theatre ticket is. Owen presupposes directly socialized labour, a form of production diametrically opposed to the production of commodities. The certificate of labour is merely

* English translation, pp. 83 ff.

The expression of the value of a commodity in gold – x commodity A = y money commodity – is its money-form or price. A single equation, such as 1 ton of iron = 2 ounces of gold, now suffices to express the value of the iron in a socially valid manner. There is no longer any need for this equation to figure as a link in the chain of equations that express the values of all other commodities, because the equivalent commodity, gold, already possesses the character of money. The general relative form of value of commodities has therefore resumed its original shape of simple or individual relative value. On the other hand, the expanded relative expression of value, the endless series of equations, has now become the specific relative form of value of the money commodity. However, the endless series itself is now a socially given fact in the shape of the prices of the commodities. We have only to read the quotations of a price-list backwards, to find the magnitude of the value of money expressed in all sorts of commodities. As against this, money has no price. In order to form a part of this uniform relative form of value of the other commodities, it would have to be brought into relation with itself as its own equivalent.

The price or money-form of commodities is, like their form of value generally, quite distinct from their palpable and real bodily form; it is therefore a purely ideal or notional form. Although invisible, the value of iron, linen and corn exists in these very articles: it is signified through their equality with gold, even though this relation with gold exists only in their heads, so to speak. The guardian of the commodities must therefore lend them his tongue, or hang a ticket on them, in order to communicate their prices to the outside world.[2] Since the expression of the value of commodi-

---

evidence of the part taken by the individual in the common labour, and of his claim to a certain portion of the common product which has been set aside for consumption. But Owen never made the mistake of presupposing the production of commodities, while, at the same time, by juggling with money, trying to circumvent the necessary conditions of that form of production.

[2] Savages and semi-savages use the tongue differently. Captain Parry says of the inhabitants of the west coast of Baffin's Bay: 'In this case (the case of barter) they licked it (the thing represented to them) twice to their tongues, after which they seemed to consider the bargain satisfactorily concluded.'* In the same way, among the Eastern Eskimo, the exchanger licked each article on

*W. E. Parry, *Journal of a Voyage for the Discovery of a North-West Passage*, London, 1821, p. 227.

ties in gold is a purely ideal act,* we may use purely imaginary or ideal gold to perform this operation. Every owner of commodities knows that he is nowhere near turning them into gold when he has given their value the form of a price or of imaginary gold, and that it does not require the tiniest particle of real gold to give a valuation in gold of millions of pounds' worth of commodities. In its function as measure of value, money therefore serves only in an imaginary or ideal capacity. This circumstance has given rise to the wildest theories.[3] But, although the money that performs the functions of a measure of value is only imaginary, the price depends entirely on the actual substance that is money. The value, i.e. the quantity of human labour, which is contained in a ton of iron is expressed by an imaginary quantity of the money commodity which contains the same amount of labour as the iron. Therefore, according to whether it is gold, silver or copper which is serving as the measure of value, the value of the ton of iron will be expressed by very different prices, or will be represented by very different quantities of those metals.

If therefore two different commodities, such as gold and silver, serve simultaneously as measures of value, all commodities will have two separate price-expressions, the price in gold and the price in silver, which will quietly co-exist as long as the ratio of the value of silver to that of gold remains unchanged, say at 15 to 1. However, every alteration in this ratio disturbs the ratio between the gold-prices and the silver-prices of commodities, and thus proves in fact that a duplication of the measure of value contradicts the function of that measure.[4]

---

receiving it. If the tongue is thus used in the North as the organ of appropriation, it is no wonder that in the South the stomach serves as the organ of accumulated property, and that a Kaffir estimates the wealth of a man by the size of his belly. The Kaffirs know what they are doing, for at the same time as the official British Health Report of 1864 was bemoaning the deficiency of fat-forming substances among a large part of the working class, a certain Dr Harvey (not, however, the man who discovered the circulation of the blood) was doing well by advertising recipes for reducing the surplus fat of the bourgeoisie and the aristocracy.

[3] See Karl Marx, *Zur Kritik etc.*, 'Theories of the Standard of Money', pp. 53 ff. [English translation, pp. 76 ff.].

[4] 'Wherever silver and gold exist side by side as legal money, i.e. as measure of value, the vain attempt has always been made to treat them as one and the

---

*In other words, it is an act which takes place entirely in the mind, and involves no physical transaction.

Commodities with definite prices all appear in this form: a commodity A $= x$ gold; b commodity B $= y$ gold; c commodity C $= z$ gold, etc., where a, b, c represent definite quantities of the commodities A, B, C and x, y, z definite quantities of gold. The values of these commodities are therefore changed into imaginary quantities of gold of different magnitudes. Hence, in spite of the confusing variety of the commodities themselves, their values become magnitudes of the same denomination, gold-magnitudes. As such, they are now capable of being compared with each other and measured, and the course of development produces the need to compare them, for technical reasons, with some fixed quantity of gold as their unit of measurement. This unit, by subsequent division into aliquot parts, becomes itself the standard of measurement. Before they become money, gold, silver and copper already possess such standards in their weights, so that, for example, a pound, which serves as a unit of measurement, can on the one hand be divided into ounces, and on the other hand be

---

same substance. If one assumes that a given labour-time must invariably be objectified in the same proportion in silver and gold, then one assumes, in fact, that gold and silver are the same substance, and that silver, the less valuable metal, represents a constant fraction of gold. From the reign of Edward III to the time of George II, the history of money in England consists of one long series of perturbations caused by the clash between the legally fixed ratio between the values of gold and silver, and the fluctuations in their real values. At one time gold was too high, at another, silver. The metal that was estimated below its value was withdrawn from circulation, melted down and exported. The ratio between the two metals was then again altered by law, but the new nominal ratio soon came into conflict, in its turn, with the real ratio. In our own times, the slight and transient fall in the value of gold compared with silver, which was a consequence of the Indian and Chinese demand for silver, produced on a far more extended scale in France the same phenomena, export of silver, and its expulsion from circulation by gold. During the years 1855, 1856 and 1857, the excess in France of gold-imports over gold-exports amounted to £41,580,000, while the excess of silver-exports over silver-imports came to £34,704,000. In fact, in countries in which both metals are legally measures of value, and therefore both legal tender, so that everyone has the option of paying in either metal, the metal that rises in value is at a premium, and, like every other commodity, measures its price in the over-valued metal which alone serves in reality as the measure of value. All the experience of history in this area can be reduced simply to this fact, that where two commodities perform by law the functions of a measure of value, in practice only one maintains that position' (Karl Marx, op. cit., pp. 52–3) [English edition, pp. 75–6].

combined with others to make up hundredweights.[5] It is owing to this that, in all metallic currencies, the names given to the standards of money or of price were originally taken from the pre-existing names of the standards of weight.

As measure of value, and as standard of price, money performs two quite different functions. It is the measure of value as the social incarnation of human labour; it is the standard of price as a quantity of metal with a fixed weight. As the measure of value it serves to convert the values of all the manifold commodities into prices, into imaginary quantities of gold; as the standard of price it measures those quantities of gold. The measure of values measures commodities considered as values; the standard of price measures, on the contrary, quantities of gold by a unit quantity of gold, not the value of one quantity of gold by the weight of another. For the standard of price, a certain weight of gold must be fixed as the unit of measurement. In this case, as in all cases where quantities of the same denomination are to be measured, the stability of the measurement is of decisive importance. Hence the less the unit of measurement (here a quantity of gold) is subject to variation, the better the standard of price fulfils its office. But gold can serve as a measure of value only because it is itself a product of labour, and therefore potentially variable in value.[6]

It is, first of all, quite clear that a change in the value of gold in no way impairs its function as a standard of price. No matter how the value of gold varies, different quantities of gold always remain in the same value-relation to each other. If the value of gold fell by 1,000 per cent, 12 ounces of gold would continue to have twelve times the value of one ounce of gold, and when we are dealing with prices we are only concerned with the relation between different quantities of gold. Since, on the other hand, an ounce of gold undergoes no change in weight when its value rises or falls, no change can take place in the weight of its aliquot parts. Thus gold always renders the same service as a fixed measure of price, however much its value may vary. Moreover, a change in the value of gold does not prevent it from fulfilling its function as measure of value. The change affects all commodities simultaneously, and therefore, other things being equal, leaves the mutual relations between their values unaltered, although those values are now all expressed in higher or lower gold-prices than before.

---

[5] The peculiar circumstance that while the ounce of gold serves in England as the unit of the standard of money, it is not divided up into aliquot parts, has been explained as follows: 'Our coinage was originally adapted to the employment of silver only, hence an ounce of silver can always be divided into a certain adequate number of pieces of coin; but as gold was introduced at a later period into a coinage adapted only to silver, an ounce of gold cannot be coined into an aliquot number of pieces' (Maclaren, *A Sketch of the History of the Currency*, London, 1858, p. 16).

[6] With English writers the confusion over measure of value and standard of price ('standard of value') is indescribable. Their functions, and therefore their names, are constantly interchanged.

Just as in the case of the estimation of the value of a commodity in the use-value of any other commodity, so also in this case, where commodities are valued in gold, we assume nothing more than that the production of a given quantity of gold costs, at a given period, a given amount of labour. As regards the fluctuations of commodity prices in general, they are subject to the laws of the simple relative expression of value which we developed in an earlier chapter.

A general rise in the prices of commodities can result either from a rise in their values, which happens when the value of money remains constant, or from a fall in the value of money, which happens when the values of commodities remain constant. The process also occurs in reverse: a general fall in prices can result either from a fall in the values of commodities, if the value of money remains constant, or from a rise in the value of money, if the values of commodities remain constant. It therefore by no means follows that a rise in the value of money necessarily implies a proportional fall in the prices of commodities, or that a fall in the value of money implies a proportional rise in prices. This would hold only for commodities whose value remains constant. But commodities whose value rises simultaneously with and in proportion to that of money would retain the same price. And if their value rose either slower or faster than that of money, the fall or rise in their prices would be determined by the difference between the path described by their value and that described by the value of money. And so on.

Let us now go back to considering the price-form. For various reasons, the money-names of the metal weights are gradually separated from their original weight-names, the historically decisive reasons being: (1) The introduction of foreign money among less developed peoples. This happened at Rome in its early days, where gold and silver coins circulated at first as foreign commodities. The names of these foreign coins were different from those of the indigenous weights. (2) With the development of material wealth, the more precious metal extrudes the less precious from its function as measure of value. Silver drives out copper, gold drives out silver, however much this sequence may contradict the chronology of the poets.[7] The word pound, for instance, was the money-name given to an actual pound weight of silver. As soon as gold had driven out silver as a measure of value, the same name became attached to, say, one fifteenth of a pound of gold, depending on the ratio between the values of gold and silver. Pound as a money-name and pound as the ordinary weight-name of gold are now two different things.[8] (3) Centuries of continuous debasement of the currency by kings and princes have in fact left nothing behind of the original weights of gold coins but their names.[9]

These historical processes have made the separation of the money-name from the weight-name into a fixed popular custom. Since the standard of money is on the one hand purely conventional, while on the other hand it must possess universal validity, it is in the end regulated by law. A given weight of one of the precious metals, an ounce of gold for instance, becomes officially divided into aliquot parts, baptized by the law as a pound, a thaler, etc. These aliquot parts, which then serve as the actual units of money, are subdivided into other aliquot parts with legal names, such as a shilling, a penny etc.[10] But, despite this, a definite weight of metal remains the standard of metallic money. All that has changed is the subdivision and the denomination of the money.

The prices, or quantities of gold, into which the values of commodities are ideally changed are therefore now expressed in the money-names, or the legally valid names of the subdivisions of the gold standard made for the purpose of reckoning. Hence, instead of saying that a quarter of wheat is worth an ounce of gold, people in England would say that it was worth £3 17s. 10½d. In this way commodities express by their money-names how much they are worth, and money serves as money of account whenever it is a question of fixing a thing as a value and therefore in its money-form.[11]

---

[7] In any case, its historical validity is not entirely universal.

[8] Thus the pound sterling denotes less than one-third of its original weight, the 'pound Scots' before the Union,* only one 36th, the French livre one 74th, the Spanish maravedi, less than one 1,000th, and the Portuguese rei a still smaller fraction.

[9] 'The coins which today have a merely ideal denomination are in all nations the oldest; once upon a time they were all real, and because they were real people reckoned with them' (Galiani, *Della Moneta*, op. cit., p. 153).

[10] David Urquhart remarks in his 'Familiar Words' on the monstrosity (!) that nowadays a pound (sterling), which is the unit of the English standard of money, is equal to about a quarter of an ounce of gold. 'This is falsifying a measure, not establishing a standard.'† In this 'false denomination' of the weight of gold, he finds what he finds everywhere else, the falsifying hand of civilization.

*The Union of Scotland with England in 1707.

†David Urquhart, *Familiar Words as Affecting England and the English*, London, 1855, p. 105.

The name of a thing is entirely external to its nature. I know nothing of a man if I merely know his name is Jacob. In the same way, every trace of the money-relation disappears in the money-names pound, thaler, franc, ducat, etc. The confusion caused by attributing a hidden meaning to these cabalistic signs is made even greater by the fact that these money-names express both the values of commodities and, simultaneously, aliquot parts of a certain weight of metal, namely the weight of the metal which serves as the standard of money.[12] On the other hand, it is in fact necessary that value, as opposed to the multifarious objects of the world of commodities, should develop into this form, a material and non-mental one, but also a simple social form.[13]

Price is the money-name of the labour objectified in a commodity. Hence the expression of the equivalence of a commodity with the quantity of money whose name is that commodity's price is a tautology,[14] just as the expression of the relative value of a commodity is an expression of the equivalence of two commodities. But although price, being the exponent of the magnitude of a commodity's value, is the exponent of its exchange-ratio with money, it does not follow that the exponent of this exchange-ratio is necessarily the exponent of the magnitude of the commodity's value. Suppose two equal quantities of socially necessary labour are respectively represented by 1 quarter of wheat and £2 (approximately ½ ounce of gold). £2 is the expression in money of the magnitude of the value of the quarter of wheat, or its price. If circumstances now allow this price to be raised to £3, or compel it to be reduced to £1, then although £1 and £3 may be too small or too large to give proper expression to the magnitude of the wheat's value, they are nevertheless prices of the wheat, for they are, in the first place, the form of its value, i.e. money, and, in the second place, the exponents of its exchange-ratio with money. If the conditions of production, or the productivity of labour, remain constant, the same amount of social labour-time must be expended on the reproduction of a quarter of wheat, both before and after the change in price. This situation is not dependent either on the will of the wheat producer or on that of the owners of the other commodities. The magnitude of the value of a commodity therefore expresses a necessary relation to social labour-time which is inherent in the process by which its value is created. With the transformation of the magnitude of value into the price this necessary relation appears as the exchange-ratio between a single commodity and the money commodity which exists outside it. This relation, however, may express both the magnitude of value of the commodity and the greater or lesser quantity of money for which it can be sold under the given circumstances. The possibility, therefore, of a quantitative incongruity between price and magnitude of value, i.e. the possibility that the price may diverge from the magnitude of value, is inherent in the price-form itself. This is not a defect, but, on the contrary, it makes this form the adequate one for a mode of production whose laws can only assert themselves as blindly operating averages between constant irregularities.

---

[11] 'When Anacharsis was asked what the Greeks used money for, he replied: for reckoning' (Athenaeus, *Deipnosophistae*, Bk IV, 49, v. 2, ed. Schweighäuser, 1802).

[12] 'Because as standard of price gold is expressed by the same names of account as the prices of commodities – for example £3 17s. 10½d. may denote an ounce of gold just as well as a ton of iron – these names of account are called the *mint-price* of gold. Thus the extraordinary notion arose that gold is estimated in its own material and that, unlike all other commodities, its price is fixed by the State. The establishing of names of account for definite weights of gold was mistaken for the establishing of the value of these weights' (Karl Marx, op. cit., p. 52) [English edition, p. 74].

[13] Cf. 'Theories of the Standard of Money', in *Zur Kritik etc.*, pp. 53 ff. [English edition, pp. 76 ff.]. Some theorists had fantastic notions of raising or lowering the 'mint-price' of money by getting the state to transfer to greater or smaller weights of gold or silver the names already legally appropriated to fixed weights of those metals, so that for example ¼ ounce of gold could be minted into 40 shillings in the future instead of 20. However, Petty dealt with these so exhaustively in his *Quantulumcunque Concerning Money: To the Lord Marquis of Halifax*, 1682, at least in those cases where they aimed not at clumsy financial operations against public and private creditors but rather at economic quack remedies, that even his immediate followers, Sir Dudley North and John Locke, not to mention later ones, could only repeat what he said more shallowly. 'If the wealth of a nation,' he remarks, 'could be decupled by a proclamation, it were strange that such proclamations have not long since been made by our Governors' (Petty, op. cit., p. 36).

---

[14] 'Or indeed it must be admitted that a million in money is worth more than an equal value in commodities' (Le Trosne, op. cit., p. 919), and hence 'that one value is worth more than another value which is equal to it'.

The price-form, however, is not only compatible with the possibility of a quantitative incongruity between magnitude of value and price, i.e. between the magnitude of value and its own expression in money, but it may also harbour a qualitative contradiction, with the result that price ceases altogether to express value, despite the fact that money is nothing but the value-form of commodities. Things which in and for themselves are not commodities, things such as conscience, honour, etc., can be offered for sale by their holders, and thus acquire the form of commodities through their price. Hence a thing can, formally speaking, have a price without having a value. The expression of price is in this case imaginary, like certain quantities in mathematics. On the other hand, the imaginary price-form may also conceal a real value-relation or one derived from it, as for instance the price of uncultivated land, which is without value because no human labour is objectified in it.

Like the relative form of value in general, price expresses the value of a commodity (for instance a ton of iron) by asserting that a given quantity of the equivalent (for instance an ounce of gold) is directly exchangeable with iron. But it by no means asserts the converse, that iron is directly exchangeable with gold. In order, therefore, that a commodity may in practice operate effectively as exchange-value, it must divest itself of its natural physical body and become transformed from merely imaginary into real gold, although this act of transubstantiation may be more 'troublesome' for it than the transition from necessity to freedom for the Hegelian 'concept', the casting of his shell for a lobster, or the putting-off of the old Adam for Saint Jerome.[15] Though a commodity may, alongside its real shape (iron, for instance), possess an ideal value-shape or an imagined gold-shape in the form of its price, it cannot simultaneously be both real iron and real gold. To establish its price it is sufficient for it to be equated with gold in the imagination. But to enable it to render its owner the service of a universal equivalent, it must be actually replaced by gold. If the owner of the iron were to go to the owner of some other earthly commodity, and were to refer him to the price of iron as proof that it was already money, his answer would be the terrestrial equivalent of the answer given by St Peter in heaven to Dante, when the latter recited the creed:

---

[15] If Jerome had to wrestle hard in his youth with the material flesh, as is shown by his fight in the desert with visions of beautiful women, he had also to wrestle in his old age with the spiritual flesh. 'I thought', he says, 'I was in the spirit before the Judge of the Universe.' 'Who art thou?' asked a voice. 'I am a Christian.' 'Thou liest,' thundered back the great Judge, 'thou art nought but a Ciceronian' [*Letter XXII, Ad Eustochium*].

> '*Assai bene è trascorsa*
> *D'esta moneta già la lega e il peso,*
> *Ma dimmi se tu l'hai nella tua borsa.*'*

The price-form therefore implies both the exchangeability of commodities for money and the necessity of exchanges. On the other hand, gold serves as an ideal measure of value only because it has already established itself as the money commodity in the process of exchange. Hard cash lurks within the ideal measure of value.

2. THE MEANS OF CIRCULATION

(a) The Metamorphosis of Commodities

We saw in a former chapter that the exchange of commodities implies contradictory and mutually exclusive conditions. The further development of the commodity does not abolish these contradictions, but rather provides the form within which they have room to move. This is, in general, the way in which real contradictions are resolved. For instance, it is a contradiction to depict one body as constantly falling towards another and at the same time constantly flying away from it. The ellipse is a form of motion within which this contradiction is both realized and resolved.

In so far as the process of exchange transfers commodities from hands in which they are non-use-values to hands in which they are use-values, it is a process of social metabolism.† The product of one kind of useful labour replaces that of another. Once a commodity has arrived at a situation in which it can serve as a use-value, it falls out of the sphere of exchange into that of consumption. But the former sphere alone interests us here. We therefore have to consider the whole process in its formal aspect, that is to

---

*'Right well hath now been tested this coin's alloy and weight; but tell me if thou hast it in thy purse' (Dante, *Divina Commedia, Paradiso*, Canto XXIV, lines 84–5).

†Here Marx introduces for the first time the concept of 'metabolism' (*Stoffwechsel*). This biological analogy plays a considerable part in his analysis of circulation and the labour process.

say, the change in form or the metamorphosis of commodities through which the social metabolism is mediated.

This change of form has been very imperfectly grasped as yet, owing to the circumstance that, quite apart from the lack of clarity in the concept of value itself, every change of form in a commodity results from the exchange of two commodities, namely an ordinary commodity and the money commodity. If we keep in mind only this material aspect, that is, the exchange of the commodity for gold, we overlook the very thing we ought to observe, namely what has happened to the form of the commodity. We do not see that gold, as a mere commodity, is not money, and that the other commodities, through their prices, themselves relate to gold as the medium for expressing their own shape in money.

Commodities first enter into the process of exchange ungilded and unsweetened, retaining their original home-grown shape. Exchange, however, produces a differentiation of the commodity into two elements, commodity and money, an external opposition which expresses the opposition between use-value and value which is inherent in it. In this opposition, commodities as use-values confront money as exchange-value. On the other hand, both sides of this opposition are commodities, hence themselves unities of use-value and value. But this unity of differences is expressed at two opposite poles, and at each pole in an opposite way. This is the alternating relation between the two poles: the commodity is in reality a use-value; its existence as a value appears only ideally, in its price, through which it is related to the real embodiment of its value, the gold which confronts it as its opposite. Inversely, the material of gold ranks only as the materialization of value, as money. It is therefore in reality exchange-value. Its use-value appears only ideally in the series of expressions of relative value within which it confronts all the other commodities as the totality of real embodiments of its utility. These antagonistic forms of the commodities are the real forms of motion of the process of exchange.

Let us now accompany the owner of some commodity, say our old friend the linen weaver, to the scène of action, the market. His commodity, 20 yards of linen, has a definite price, £2. He exchanges it for the £2, and then, being a man of the old school, he parts for the £2 in return for a family Bible of the same price. The linen, for him a mere commodity, a bearer of value, is alienated in exchange for gold, which is the shape of the linen's value, then it is taken out of this shape and alienated again in exchange for another commodity, the Bible, which is destined to enter the weaver's house as an object of utility and there to satisfy his family's need for edification. The process of exchange is therefore accomplished through two metamorphoses of opposite yet mutually complementary character – the conversion of the commodity into money, and the re-conversion of the money into a commodity.[16] The two moments of this metamorphosis are at once distinct transactions by the weaver – selling, or the exchange of the commodity for money, and buying, or the exchange of the money for a commodity – and the unity of the two acts: selling in order to buy.

The end result of the transaction, from the point of view of the weaver, is that instead of being in possession of the linen, he now has the Bible; instead of his original commodity, he now possesses another of the same value but of different utility. He procures his other means of subsistence and of production in a similar way. For the weaver, the whole process accomplishes nothing more than the exchange of the product of his labour for the product of someone else's, nothing more than an exchange of products.

The process of exchange is therefore accomplished through the following changes of form:

Commodity–Money–Commodity
C–M–C

As far as concerns its material content, the movement is C–C, the exchange of one commodity for another, the metabolic interaction of social labour, in whose result the process itself becomes extinguished.

C–M. First metamorphosis of the commodity, or sale. The leap taken by value from the body of the commodity into the body of the gold is the commodity's *salto mortale*, as I have called it elsewhere.* If the leap falls short, it is not the commodity which is de-

[16] 'ἐκ δὲ τοῦ . . . πυρὸς τ'ἀνταμείβεσθαι πάντα, φησὶν ὁ 'Ηράκλειτος, και πῦρ ἁπαντων, ὥσπερ χρυσοῦ χρήματα καί χρημάτων χρυσός' (F. Lassalle, *Die Philosophie Herakleitos des Dunkeln*, Berlin, 1858, Vol. 1, p. 222).* Lassalle, in his note on this passage, p. 224, n. 3, erroneously makes money a mere symbol of value.

*'As Heracleitus says, all things exchange for fire, and fire for all things, just as gold does for goods and goods for gold' (Plutarch, *Moralia*, 'The E at Delphi', 388D).

---

* See *A Contribution to the Critique of Political Economy*, p. 88.

frauded but rather its owner. The social division of labour makes the nature of his labour as one-sided as his needs are many-sided. This is precisely the reason why the product of his labour serves him solely as exchange-value. But it cannot acquire universal social validity as an equivalent-form except by being converted into money. That money, however, is in someone else's pocket. To allow it to be drawn out, the commodity produced by its owner's labour must above all be a use-value for the owner of the money. The labour expended on it must therefore be of a socially useful kind, i.e. it must maintain its position as a branch of the social division of labour. But the division of labour is an organization of production which has grown up naturally, a web which has been, and continues to be, woven behind the backs of the producers of commodities. Perhaps the commodity is the product of a new kind of labour, and claims to satisfy a newly arisen need, or is even trying to bring forth a new need on its own account. Perhaps a particular operation, although yesterday it still formed one out of the many operations conducted by one producer in creating a given commodity, may today tear itself out of this framework, establish itself as an independent branch of labour, and send its part of the product to market as an independent commodity. The circumstances may or may not be ripe for such a process of separation. Today the product satisfies a social need. Tomorrow it may perhaps be expelled partly or completely from its place by a similar product. Moreover, although our weaver's labour may be a recognized branch of the social division of labour, yet that fact is by no means sufficient to guarantee the utility of his 20 yards of linen. If the society's need for linen – and such a need has a limit like every other need – has already been satisfied by the products of rival weavers, our friend's product is superfluous, redundant and consequently useless. Although people do not look a gift-horse in the mouth, our friend does not frequent the market to make presents of his products. Let us assume, however, that the use-value of his product does maintain itself, and that the commodity therefore attracts money. Now we have to ask: how much money? No doubt the answer is already anticipated in the price of the commodity, which is the exponent of the magnitude of its value. We leave out of consideration here any possible subjective errors in calculation by the owner of the commodity, which will immediately be corrected objectively in the market. We suppose him to have spent on his product only the average socially necessary quantity of labour-time. The price of the commodity, therefore, is merely the money-name of the quantity of social labour objectified in it. But now the old-established conditions of production in weaving are thrown into the melting-pot, without the permission of, and behind the back of, our weaver. What was yesterday undoubtedly labour-time socially necessary to the production of a yard of linen ceases to be so today, a fact which the owner of the money is only too eager to prove from the prices quoted by our friend's competitors. Unluckily for the weaver, people of his kind are in plentiful supply. Let us suppose, finally, that every piece of linen on the market contains nothing but socially necessary labour-time. In spite of this, all these pieces taken as a whole may contain superfluously expended labour-time. If the market cannot stomach the whole quantity at the normal price of 2 shillings a yard, this proves that too great a portion of the total social labour-time has been expended in the form of weaving. The effect is the same as if each individual weaver had expended more labour-time on his particular product than was socially necessary. As the German proverb has it: caught together, hung together. All the linen on the market counts as one single article of commerce, and each piece of linen is only an aliquot part of it. And in fact the value of each single yard is also nothing but the materialization of the same socially determined quantity of homogeneous human labour.*

We see then that commodities are in love with money, but that 'the course of true love never did run smooth'. The quantitative articulation [*Gliederung*] of society's productive organism, by which its scattered elements are integrated into the system of the division of labour, is as haphazard and spontaneous as its qualitative articulation. The owners of commodities therefore find out that the same division of labour which turns them into independent private producers also makes the social process of production and the relations of the individual producers to each other within that process independent of the producers themselves; they also find out that the independence of the individuals from each other has as

---

*In a letter of 28 November 1878 to N. F. Danielson, the Russian translator of *Capital*, Marx made the following alteration to this sentence: 'And in fact the value of each single yard is also nothing but the materialization of a part of the quantity of social labour expended in the whole amount of the linen.' An analogous correction was made in a copy of the second German edition of the first volume of *Capital* which belonged to Marx; however this was not in his handwriting. [Note by the Institute of Marxism-Leninism] its counterpart and supplement a system of all-round material dependence.

The division of labour converts the product of labour into a commodity, and thereby makes necessary its conversion into money. At the same time, it makes it a matter of chance whether this transubstantiation succeeds or not. Here, however, we have to look at the phenomenon in its pure shape, and must therefore assume it has proceeded normally. In any case, if the process is to take place at all, i.e. if the commodity is not impossible to sell, a change of form must always occur, although there may be an abnormal loss or accretion of substance – that is, of the magnitude of value.

The seller has his commodity replaced by gold, the buyer has his gold replaced by a commodity. The striking phenomenon here is that a commodity and gold, 20 yards of linen and £2, have changed hands and places, in other words that they have been exchanged. But what is the commodity exchanged for? For the universal shape assumed by its own value. And what is the gold exchanged for? For a particular form of its own use-value. Why does gold confront the linen as money? Because the linen's price of £2, its money-name, already brings it into relation with the gold as money. The commodity is divested of its original form through its sale, i.e. the moment its use-value actually attracts the gold, which previously had a merely imaginary existence in its price. The realization of a commodity's price, or of its merely ideal value-form, is therefore at the same time, and inversely, the realization of the merely ideal use-value of money; the conversion of a commodity into money is the conversion of money into a commodity. This single process is two-sided: from one pole, that of the commodity-owner, it is a sale, from the other pole, that of the money-owner, it is a purchase. In other words, a sale is a purchase, C–M is also M–C.[17]

Up to this point we have considered only one economic relation between men, a relation between owners of commodities in which they appropriate the produce of the labour of others by alienating [*entfremden*] the produce of their own labour. Hence, for one commodity-owner to meet with another, in the form of a money-owner, it is necessary either that the product of the latter should possess by its nature the form of money, i.e. it should be gold, the material of which money consists, or that his product should already have changed its skin and stripped off its original form of a useful object. In order to function as money, gold must of course enter the market at some point or other. This point is to be found at its source of production, where the gold is exchanged, as the immediate product of labour, for some other product of equal value. But from that moment onwards, it always represents the realized price of some commodity.[18] Leaving aside its exchange for other commodities at the source of production, gold is, in the hands of every commodity-owner, his own commodity divested [*entäussert*] of its original shape by being alienated [*veräussert*];* it is the product of a sale or of the first metamorphosis C–M.[19] Gold, as we saw, became ideal money, or a measure of value, because all commodities measured their values in it, and thus made it the imaginary opposite of their natural shape as objects of utility, hence the shape of their value. It became real money because the commodities, through their complete alienation, suffered a divestiture or transformation of their real shapes as objects of utility, thus making it the real embodiment of their values. When they thus assume the shape of values, commodities strip off every trace of their natural and original use-value, and of the particular kind of useful labour to which they owe their creation, in order to pupate into the homogeneous social materialization of undifferentiated human labour. From the mere look of a piece of money, we cannot tell what breed of commodity has been transformed into it. In their money-form all commodities look alike. Hence money may be dirt, although dirt is not money. We will assume that the two golden coins in return for which our weaver has parted with his linen are the metamorphosed shape of a quarter of wheat. The sale of the linen, C–M, is at the same time its purchase, M–C. But this process, considered as the sale of the linen, starts off a move-

---

[17] 'Every sale is a purchase' (Dr Quesnay, *Dialogues sur le commerce et les travaux des artisans*, *Physiocrates*, ed. Daire, Part 1, Paris, 1846, p. 170), or, as Quesnay says in his *Maximes générales*, 'To sell is to buy.'*

*This quotation appears in Dupont de Nemours, *Maximes du docteur Quesnay*, printed in *Physiocrates*, ed. Daire, Part 1, Paris, 1846, p. 392.

[18] 'The price of one commodity can only be paid by the price of another commodity' (Mercier de la Rivière, *L'Ordre naturel et essentiel des sociétés politiques, Physiocrates*, ed. Daire, Part 2, p. 554).

[19] 'In order to have this money, one must have made a sale.' (ibid., p. 543).

---

* Cf. *Grundrisse*, p. 196: 'Appropriation through and by means of divestiture [*Entäusserung*] and alienation [*Veräusserung*] is the fundamental condition of commodity circulation.'

ment which ends with its opposite: the purchase of a Bible. Considered as purchase of the linen, on the other hand, the process completes a movement which began with its opposite, the sale of the wheat. C–M (linen–money), which is the first phase of C–M–C (linen–money–Bible), is also M–C (money–linen), the last phase of another movement C–M–C (wheat–money–linen). The first metamorphosis of one commodity, its transformation from the commodity-form into money, is therefore also invariably the second, and diametrically opposite, metamorphosis of some other commodity, the retransformation of the latter from money into a commodity.[20]

M–C. The second or concluding metamorphosis of the commodity: purchase. Money is the absolutely alienable commodity, because it is all other commodities divested of their shape, the product of their universal alienation. It reads all prices backwards, and thus as it were mirrors itself in the bodies of all other commodities, which provide the material through which it can come into being as a commodity. At the same time the prices, those wooing glances cast at money by commodities, define the limit of its convertibility, namely its own quantity. Since every commodity disappears when it becomes money it is impossible to tell from the money itself how it got into the hands of its possessor, or what article has been changed into it. *Non olet*,* from whatever source it may come. If it represents, on the one hand, a commodity which has been sold, it also represents, on the other hand, a commodity which can be bought.[21]

M–C, a purchase, is at the same time C–M, a sale; the concluding metamorphosis of one commodity is the first metamorphosis of another. For our weaver, the life of his commodity ends with the Bible into which he has reconverted his £2. But suppose the seller of the Bible turns the £2 set free by the weaver into brandy. M–C, the concluding phase of C–M–C (linen–money–Bible), is also C–M, the first phase of C–M–C (Bible–money–

[20] As remarked previously, the actual producer of gold or silver forms an exception. He exchanges his product without having first sold it.

[21] 'If money represents, in our hands, the things we can wish to buy, it also represents the things we have sold for this money' (Mercier de la Rivière, op. cit., p. 586).

---

*'It (money) has no smell.' This is alleged to have been the reply of the Roman Emperor Vespasian to his son Titus, when the latter reproached him for obtaining money by taxing the public lavatories.

brandy). Since the producer of the commodity offers only a single product, he often sells it in large quantities, whereas the fact that he has many needs compels him to split up the price realized, the sum of money set free, into numerous purchases. Hence a sale leads to many purchases of different commodities. The concluding metamorphosis of a commodity thus constitutes an aggregate of the first metamorphoses of other commodities.

If we now consider the completed metamorphosis of a commodity as a whole, it appears in the first place that it is made up of two opposite and complementary movements, C–M and M–C. These two antithetical transmutations of the commodity are accomplished through two antithetical social processes in which the commodity-owner takes part, and are reflected in the antithetical economic characteristics of the two processes. By taking part in the act of sale, the commodity-owner becomes a seller; in the act of purchase, he becomes a buyer. But just as, in every transmutation of a commodity, its two forms, the commodity-form and the money-form, exist simultaneously but at opposite poles, so every seller is confronted with a buyer, every buyer with a seller. While the same commodity is successively passing through the two inverted transmutations, from a commodity into money and from money into another commodity, the owner of the commodity successively changes his role from seller to buyer. Being a seller and being a buyer are therefore not fixed roles, but constantly attach themselves to different persons in the course of the circulation of commodities.

The complete metamorphosis of a commodity, in its simplest form, implies four *dénouements* and three *dramatis personae.* First, a commodity comes face to face with money; the latter is the form taken by the value of the former, and exists over there in someone else's pocket in all its hard, material reality. A commodity-owner is thus confronted with a money-owner. Now as soon as the commodity has been changed into money, the money becomes its vanishing equivalent-form, whose use-value or content exists here on the spot, in the bodies of other commodities. Money, the final stage of the first transformation, is at the same time the starting-point for the second. The person who is a seller in the first transaction thus becomes a buyer in the second, in which a third commodity-owner comes to meet him as a seller.[22]

[22] 'There are accordingly . . . four final terms and three contracting parties, one of whom intervenes twice' (Le Trosne, op. cit., p. 909).

The two inverted phases of the movement which makes up the metamorphosis of a commodity constitute a circuit: commodity-form, stripping off of this form, and return to it. Of course, the commodity itself is here subject to contradictory determinations. At the starting-point it is a non-use-value to its owner; at the end it is a use-value. So too the money appears in the first phase as a solid crystal of value into which the commodity has been transformed, but afterwards it dissolves into the mere equivalent-form of the commodity.

The two metamorphoses which constitute the commodity's circular path are at the same time two inverse partial metamorphoses of two other commodities. One and the same commodity (the linen) opens the series of its own metamorphoses, and completes the metamorphosis of another (the wheat). In its first transformation, the sale, the linen plays these two parts in its own person. But then it goes the way of all flesh, enters the chrysalis state as gold, and thereby simultaneously completes the first metamorphosis of a third commodity. Hence the circuit made by one commodity in the course of its metamorphoses is inextricably entwined with the circuits of other commodities. This whole process constitutes the circulation of commodities.

The circulation of commodities differs from the direct exchange of products not only in form, but in its essence. We have only to consider the course of events. The weaver has undoubtedly exchanged his linen for a Bible, his own commodity for someone else's. But this phenomenon is only true for him. The Bible-pusher, who prefers a warming drink to cold sheets, had no intention of exchanging linen for his Bible; the weaver did not know that wheat had been exchanged for his linen. B's commodity replaces that of A, but A and B do not mutually exchange their commodities. It may in fact happen that A and B buy from each other, but a particular relationship of this kind is by no means the necessary result of the general conditions of the circulation of commodities. We see here, on the one hand, how the exchange of commodities breaks through all the individual and local limitations of the direct exchange of products, and develops the metabolic process of human labour. On the other hand, there develops a whole network of social connections of natural origin, entirely beyond the control of the human agents. Only because the farmer has sold his wheat is the weaver able to sell his linen, only because the weaver has sold his linen is our rash and intemperate friend able to sell his Bible, and only because the latter already has the water of everlasting life is the distiller able to sell his *eau-de-vie.* And so it goes on.

The process of circulation, therefore, unlike the direct exchange of products, does not disappear from view once the use-values have changed places and changed hands. The money does not vanish when it finally drops out of the series of metamorphoses undergone by a commodity. It always leaves behind a precipitate at a point in the arena of circulation vacated by the commodities. In the complete metamorphosis of the linen, for example, linen–money–Bible, the linen first falls out of circulation, and money steps into its place. Then the Bible falls out of circulation, and again money takes its place. When one commodity replaces another, the money commodity always sticks to the hands of some third person.[23] Circulation sweats money from every pore.

Nothing could be more foolish than the dogma that because every sale is a purchase, and every purchase a sale, the circulation of commodities necessarily implies an equilibrium between sales and purchases. If this means that the number of actual sales accomplished is equal to the number of purchases, it is a flat tautology. But its real intention is to show that every seller brings his own buyer to market with him. Sale and purchase are one identical act, considered as the alternating relation between two persons who are in polar opposition to each other, the commodity-owner and the money-owner. They constitute two acts, of polar and opposite character, considered as the transactions of one and the same person. Hence the identity of sale and purchase implies that the commodity is useless if, when it is thrown into the alchemist's retort of circulation, it does not come out again as money; if, in other words, it cannot be sold by its owner, and therefore bought by the owner of the money. This identity further implies that the process, if it reaches fruition, constitutes a point of rest, an interval, long or short, in the life of the commodity. Since the first metamorphosis of a commodity is at once a sale and a purchase, this partial process is at the same time an independent process in itself. The buyer has the commodity, the seller has the money, i.e. a commodity which remains in a form capable of circulating, whether it reappears on the market at an earlier or later date. No one can sell unless someone else purchases. But no one directly needs to

---

[23] This phenomenon may be self-evident, but it is in most cases overlooked by political economists, especially by the average free-trader.

purchase because he has just sold. Circulation bursts through all the temporal, spatial and personal barriers imposed by the direct exchange of products, and it does this by splitting up the direct identity present in this case between the exchange of one's own product and the acquisition of someone else's into the two antithetical segments of sale and purchase. To say that these mutually independent and antithetical processes form an internal unity is to say also that their internal unity moves forward through external antitheses. These two processes lack internal independence because they complement each other. Hence, if the assertion of their external independence [*äusserliche Verselbständigung*] proceeds to a certain critical point, their unity violently makes itself felt by producing – a crisis. There is an antithesis, immanent in the commodity, between use-value and value, between private labour which must simultaneously manifest itself as directly social labour, and a particular concrete kind of labour which simultaneously counts as merely abstract universal labour, between the conversion of things into persons and the conversion of persons into things*; the antithetical phases of the metamorphosis of the commodity are the developed forms of motion of this immanent contradiction. These forms therefore imply the possibility of crises, though no more than the possibility. For the development of this possibility into a reality a whole series of conditions is required, which do not yet even exist from the standpoint of the simple circulation of commodities.[24]

[24] See my observations on James Mill in *Zur Kritik etc.*, pp. 74–6 [English translation, pp. 96–8]. There are two points here which are characteristic of the method of the bourgeoisie's economic apologists. The first is the identification of the circulation of commodities with the direct exchange of products, achieved simply by abstracting from their differences. The second is the attempt to explain away the contradictions of the capitalist process of production by dissolving the relations between persons engaged in that process of production into the simple relations arising out of the circulation of commodities. The production and circulation of commodities are however phenomena which are to be found in the most diverse modes of production, even if they vary in extent and importance. If we are only familiar with the abstract categories of circulation, which are common to all of them, we cannot know anything of their *differentia specifica*, and we cannot therefore pronounce judgement on them. In no science other than political economy does there prevail such a combina-

(b) The Circulation of Money

The change of form through which the metabolism of the products of labour is accomplished, C–M–C, requires that a given value shall form the starting-point of the process, in the shape of a commodity, and that it shall return to the same point in the shape of a commodity. This movement of commodities is therefore a circuit. On the other hand, the form of this movement excludes money from the circuit. The result of the movement is not the return of the money, but its continued removal further and further away from its starting-point. As long as the seller sticks fast to his money, which is the transformed shape of his commodity, that commodity is still at the stage of the first metamorphosis, in other words it has completed only the first half of its circulatory course. Once the process of selling in order to buy is complete the money again leaves the hands of its original possessor. Of course, if the weaver, having bought the Bible, sells more linen, money comes back into his hands. But this return is not a result of the circulation of the first 20 yards of linen; that circulation rather removed money from the hands of the weaver and placed it in those of the Bible-pusher. The return of money to the weaver results only from the renewal or repetition of the same process of circulation with a fresh commodity, and it ends in the same way as the previous process. Hence the movement directly imparted to money by the circulation of commodities takes the form of a constant removal from its starting-point, a path followed from the hands of one commodity-owner into those of another. This path is its circulation (currency, *cours de la monnaie*).*

The circulation of money is the constant and monotonous re-

---

tion of great self-importance with the mouthing of elementary commonplaces. For instance, J. B. Say sets himself up as a judge of crises because he knows that a commodity is a product.*

*'The conception adopted by Ricardo from the tedious Say, that overproduction is not possible or at least that no general glut of the market is possible, is based on the proposition that products are exchanged against products' (*Theories of Surplus-Value*, Part 2, p. 493). In his *Traité d'économie politique*, Vol. 2, Paris, 1814, p. 382, Say writes: 'Products can only be bought with products.'

---

*We have chosen to regard the words in parentheses as explanatory synonyms rather than suggested translations of the German word '*Umlauf*'. The use of the word 'currency' for 'circulation of money' was old-fashioned even in 1867.

petition of the same process. The commodity is always in the hands of the seller; the money, as a means of purchase, always in the hands of the buyer. And money serves as a means of purchase by realizing the price of the commodity. By doing this, it transfers the commodity from the seller to the buyer, and removes the money from the hands of the buyer into those of the seller, where it again goes through the same process with another commodity. That this one-sided form of motion of the money arises out of the two-sided form of motion of the commodity is a circumstance which is hidden from view. The very nature of the circulation of commodities produces a semblance of the opposite. The first metamorphosis of a commodity is visibly not only the money's movement, but also that of the commodity itself; in the second metamorphosis, on the contrary, the movement appears to us as the movement of the money alone. In the first phase of its circulation the commodity changes places with the money. Thereupon the commodity, in its shape as an object of utility, falls out of circulation into consumption.[25] Its value-shape or monetary larva steps into its shoes. It then passes through the second phase of its circulation, no longer in its own natural shape, but in its monetary shape. With this, the continuity of the movement depends entirely on the money, and the same movement which, for the commodity, includes two opposed processes, is, when considered as the movement of the money, always one and the same process, a constant change of places with commodities which are always different. Hence the result of the circulation of commodities, namely the replacement of one commodity by another, appears not to have been mediated by its own change of form, but rather by the function of money as means of circulation. As means of circulation, money circulates commodities, which in and for themselves lack the power of movement, and transfers them from hands in which they are non-use-values into hands in which they are use-values; and this process always takes the opposite direction to the path of the commodities themselves. Money constantly removes commodities from the sphere of circulation, by constantly stepping into their place in circulation, and in this way continually moving away from its own starting-point. Hence although the movement of money is merely the expression of the circulation of commodities, the situation appears to be the reverse of this, namely the circulation of commodities seems to be the result of the movement of money.[26]

---

[25] Even when the commodity is sold over and over again, a situation we are not yet concerned with, it falls, when definitely sold for the last time, out of the sphere of circulation into that of consumption, where it serves either as means of subsistence or means of production.

Again, money functions as a means of circulation only because in it the value possessed by commodities has taken on an independent shape. Hence its movement, as the medium of circulation, is in fact merely the movement undergone by commodities while changing their form. This fact must therefore make itself plainly visible in the circulation of money. (Thus the linen, for instance, first of all changes its commodity-form into its money-form. The final term of its first metamorphosis C–M, the money-form, then becomes the first term of its final metamorphosis M–C, its transformation back into the shape of the Bible. But each of these two changes of form is accomplished by an exchange between commodity and money, by their reciprocal displacement. The same pieces of coin come into the seller's hand as the alienated form of the commodity and leave it as the commodity in its absolutely alienable form. They are displaced twice. The first metamorphosis of the linen puts these coins into the weaver's pocket, the second draws them out of it. The two opposite changes undergone by the same commodity are reflected in the displacement, twice repeated but in opposite directions, of the same pieces of coin.

If however only a one-sided metamorphosis takes place, if there are only sales or only purchases, then a given piece of money changes its place only once. Its second change of place always expresses the second metamorphosis of the commodity, its reconversion from money. The frequently repeated displacement of the same coins reflects not only the series of metamorphoses undergone by a single commodity, but also the mutual entanglement of the innumerable metamorphoses in the whole world of commodities.)* It is in any case evident that all this is valid only for the simple circulation of commodities, the form we are considering here.

Every commodity, when it first steps into circulation and under-

[26] 'It [money] has no other motion than that with which it is endowed by the products' (Le Trosne, op. cit., p. 885).

---

*The passage in parentheses is an expanded version of Marx's original argument, inserted by Engels into the fourth German edition.

goes its first change of form, does so only to fall out of circulation once more and be replaced again and again by fresh commodities. Money, on the contrary, as the medium of circulation, haunts the sphere of circulation and constantly moves around within it. The question therefore arises of how much money this sphere continuously absorbs.

In a given country there take place every day at the same time, though in different places, numerous one-sided metamorphoses of commodities; in other words, simple sales on one hand, simple purchases on the other. In their prices, the commodities have already been equated with definite but imaginary quantities of money. And since, in the direct form of circulation being considered here, money and commodities always come into physical confrontation with each other, one at the positive pole of purchase, the other at the negative pole of sale, it is clear that the amount of means of circulation required is determined beforehand by the sum of the prices of all these commodities. As a matter of fact, the money is only the representation in real life of the quantity of gold previously expressed in the imagination by the sum of the prices of the commodities. It is therefore self-evident that these two quantities are equal. We know however that, the values of commodities remaining constant, their prices vary with the value of gold (the material of money), rising in proportion as it falls, and falling in proportion as it rises. Given that the sum of the prices of commodities falls or rises in this way, it follows that the quantity of money in circulation must fall or rise to the same extent. This change in the quantity of the circulating medium is certainly caused by the money itself, yet not in virtue of its function as a medium of circulation, but rather in virtue of its function as a measure of value. First the price of the commodities varies inversely as the value of the money, and then the quantity of the medium of circulation varies directly as the price of the commodities. Exactly the same phenomenon would arise if, for instance, instead of the value of gold falling, silver were to replace it as the measure of value, or if, instead of the value of silver rising, it were to be driven out of its function as measure of value by gold. In the one case, more silver would be in circulation than there was previously gold, and in the other case, less gold would be in circulation than there was previously silver. In each case the value of the money material, i.e. the value of the commodity serving as the measure of value, would have undergone a change, and so too, therefore, would the prices of commodities which express their values in money, as well as the quantity of money which would need to be in circulation to realize those prices. We have already seen that the sphere of circulation has a gap in it, through which gold (or silver, or the money material in general) enters as a commodity with a given value. Hence, when money begins to function as a measure of value, when it is used to determine prices, its value is presupposed. If that value falls, the fall first shows itself in a change in the prices of those commodities which are directly exchanged with the precious metals at their source. The greater part of all other commodities, especially at the less developed stages of bourgeois society, will continue for a long time to be estimated in terms of the former value of the measure of value, which has now become antiquated and illusory. Nevertheless, one commodity infects another through their common value-relation, so that their prices, expressed in gold or silver, gradually settle down into the proportions determined by their comparative values, until finally the values of all commodities are estimated in terms of the new value of the monetary metal. This process of equalization is accompanied by a continued increase in the quantity of the precious metals, owing to the influx needed to replace the commodities directly exchanged with them. In proportion therefore as the adjusted prices of the commodities become universal, in proportion as their values come to be estimated according to the new value of the metal (which has fallen and may, up to a certain point, continue to fall), in that same proportion does the increased mass of metal which is necessary for the realization of the new prices become available. A one-sided observation of the events which followed the discovery of fresh supplies of gold and silver led some people in the seventeenth and more particularly in the eighteenth century to the false conclusion that the prices of commodities had risen because there was more gold and silver acting as the means of circulation. Henceforth we shall assume the value of gold as a given factor, as in fact it is if we take it at the moment when we estimate the price of a commodity.

On this assumption, then, the quantity of the medium of circulation is determined by the sum of the prices to be realized. If we now further assume that the price of each commodity is given, the sum of the prices clearly depends on the total amount of commodities found in circulation. We do not need to rack our brains to grasp that if our quarter of wheat costs £2, 100 quarters will cost

ers £400, and so on, and therefore that the quantity
changes places with the wheat, when it is sold,
the quantity of the wheat increases.
f commodities remains constant, the quantity of
ation surges up or down according to the fluctua-
es of the commodities. It rises and falls because the
s increases or diminishes as a result of the change
is it is by no means necessary that the prices of
should rise or fall simultaneously. A rise or a
of a number of leading articles is sufficient in the
ease, in the other to diminish, the sum of the prices
ties, and therefore to put more or less money in
ether the change in the price reflects an actual
alue of the commodities, or merely fluctuations in
ces, the effect on the quantity of the medium of cir-
s the same.
e that there occur a number of unconnected and
les, or partial metamorphoses, in different locali-
y, 1 quarter of wheat, 20 yards of linen, 1 Bible
f brandy. If the price of each article is £2, and
prices to be realized is consequently £8, it follows
y must enter into circulation. If, on the other hand,
les are links in the following chain of metamor-
er of wheat – £2 – 20 yards of linen – £2 – 1 Bible –
brandy – £2, a chain which is already well known
the £2 causes the different commodities to circulate
eir prices successively, and therefore realizing the
ices, which is £8, the £2 finally comes to rest in the
stiller. The £2 has turned over four times. It has
acts of circulation. This repeated change of place
es of money corresponds to the double change of
by the commodities, it corresponds to their move-
vo diametrically opposed stages of circulation, and
of the metamorphoses of different commodities.[27]
al and mutually complementary phases, through
ss passes, cannot take place alongside each other.

e, op. cit., pp. 915–16).

therefore which form the measure of the duration of the process, in other words, the velocity of the circulation of money is measured by the number of times the same piece of money turns over within a given period. Suppose the process of circulation of the four articles takes a day. The sum of prices to be realized is £8, the number of times the £2 turns over during the day is four, and the quantity of money in circulation is £2. Hence, for a given interval of time during the process of circulation, we have the following equation: the quantity of money functioning as the circulating medium = the sum of the prices of the commodities divided by the number of times coins of the same denomination turn over. This law holds generally. The process of circulation in a given country is made up, on the one hand, of numerous isolated and simultaneous partial metamorphoses, sales (and purchases) running parallel to each other in which each coin changes its position only once, or performs only one act of circulation; on the other hand, it is made up of many distinct series of metamorphoses, partly running parallel, partly coalescing with each other, and in each of these series each coin turns over a number of times. How often each coin turns over varies according to the circumstances. Given the total number of times all the circulating coins of one denomination turn over, we can arrive at the average number of times a single coin turns over, or, in other words, the average velocity of circulation of money. The quantity of money thrown into the process of circulation at the beginning of each day is of course determined by the sum of the prices of all the commodities circulating simultaneously and side by side. But within that process coins are, so to speak, made responsible for each other. If one increases its velocity of circulation, the other slows down or completely leaves the sphere of circulation. This is because the sphere of circulation can absorb only the amount of gold which, multiplied by the average number of times its basic unit turns over, is equal to the sum of prices to be realized. Hence, if the number of acts of circulation performed by the separate pieces increases, the total number of those pieces in circulation diminishes. If the number of acts of circulation diminishes, the total number of pieces increases. Since the quantity of money which can function as means of circulation is fixed for a given average velocity of circulation, one has only to throw a given quantity of £1 notes into circulation in order to extract the same number of sovereigns from it. This trick is well known to all banks.

Just as the circulation of money is in general merely a reflection of the process of circulation of commodities, i.e. their circular path through diametrically opposed metamorphoses, so too the velocity of circulation of money is merely a reflection of the rapidity with which commodities change their forms, the continuous interlocking of the series of metamorphoses, the hurried nature of society's metabolic process, the quick disappearance of commodities from the sphere of circulation, and their equally quick replacement by fresh commodities. In the velocity of circulation, therefore, there appears the fluid unity of the antithetical and complementary phases, i.e. the transformation of the commodities from the form of utility into the form of value and their re-transformation in the reverse direction, or the two processes of sale and purchase. Inversely, when the circulation of money slows down, the two processes become separated, they assert their independence and mutual antagonism; stagnation occurs in the changes of form, and hence in the metabolic process. The circulation itself, of course, gives no clue to the origin of this stagnation; it merely presents us with the phenomenon. Popular opinion is naturally inclined to attribute this phenomenon to a quantitative deficiency in the circulating medium, since it sees money appear and disappear less frequently at all points on the periphery of circulation, in proportion as the circulation of money slows down.[28]

The total quantity of money functioning during a given period as the circulating medium is determined on the one hand by the sum of the prices of the commodities in circulation, and on the other hand by the rapidity of alternation of the antithetical processes of circulation. The proportion of the sum of the prices which can on average be realized by each single coin depends on this rapidity of alternation. But the sum of the prices of the commodities depends on the quantity, as well as on the price, of each kind of commodity. These three factors, the movement of prices, the quantity of commodities in circulation, and the velocity of circulation of money, can all vary in various directions under different conditions. Hence the sum of the prices to be realized, and consequently the quantity of the circulating medium conditioned by that sum, will vary with the very numerous variations of the three factors in combination. Here we shall outline only the most important variations in the history of commodity prices.
